NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JUNE 23, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., the Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

We begin our hearings today with Dr. Leland J. Haworth as our first witness. Will you come forward, please, Dr. Haworth.

I am particularly pleased not only to have Dr. Haworth as our first witness at these hearings, but I am also happy that the chairman of the full committee, Mr. George P. Miller, is here with us. I would appreciate it, Mr. Chairman, if you would make the opening remarks.

Thank you, Mr. Daddario.

Mr. MILLER. I am very happy to be here and to welcome Dr. Haworth and his staff. Ever since this committee was formed we have been aware of our specific responsibilities toward the National Science Foundation and our legislative duty to oversee the Foundation's activities and programs.

For two reasons, however, we have not up to this point undertaken more than an annual briefing session with Foundation officials.

One reason was that the national space program—also our specific responsibility—was just getting underway and needed an inordinate amount of attention. Both the stakes and the costs were very high, so that we on the committee had no choice except to devote our time almost exclusively to the space endeavor.

The second reason was that the Foundation itself was in the midst of a transition, with a change of leadership and other personnel—and it appeared best not to begin a general review of the Foundation until the incoming group had a chance to get its bearings and become oriented to the problems facing it.

Nonetheless, almost 3 years ago Mr. Daddario and I began discussing the advisability of a complete and thorough review of the Foundation's mission—one that would be critical but constructive. At that time I indicated I would like him to chair a subcommittee to undertake the task just as soon as the proper moment arrived. Mr. Daddario concurred and, I know, has long had these hearings scheduled on the agenda of this subcommittee.

The appropriate moment is now here.

It is my hope and belief that these hearings will prove helpful and beneficial to the Foundation and, through it, to the American and International Scientific Community. The Foundation is a most important balance wheel in our national scientific and technological effort. It should have the benefit of our understanding and whatever assistance the Congress can give.

I want to congratulate you on getting these hearings underway. I am sure that they will be fruitful.

Thank you.

Mr. DADDARIO. Thank you, Mr. Chairman.

At the outset of these hearings I should like to pay special tribute to the leadership of Chairman Miller in inaugurating these hearings and supporting their preparation. We are particularly indebted to him for providing sufficient time, staff help, and consultation to do the job which is to be done.

We also are grateful for his perception and patience.

Underlying this review is the realization that many things have changed in the past 15 years. The concepts of the Foundation and the mission given to it by Congress in 1950 have proved their validity. They desire, however, reexamination at this point in time.

It is the job of the committee to do this and, if changes appear warranted, to bring about new legislation which will effect the necessary revisions.

In this effort we hope to have the help of those most cognizant of the Foundation's activities and goals, both in Government and out. Hence we have arranged to hear some 40 witnesses, beginning today with the Foundation's distinguished director, Dr. Leland J. Haworth.

As we proceed with the hearings, we would do well to keep in mind how rapidly the National Science Foundation has grown. To me, this suggests the scope of the Nation's need for the Foundation's services. In 15 years the National Science Foundation budget has increased from about a quarter of a million dollars to half a billion dollars.

It would be hard, indeed, for an agency to sustain growth at this rate without experiencing some problems.

So we hope to establish some helpful evidence in at least three major categories.

(1) How well has the National Science Foundation performed the tasks which Congress set out for it in the basic act of 1950?

(2) What roles, responsibilities, and missions should the National Science Foundation assume in the future?

(3) What tools will the Foundation need in the years ahead to accomplish its work?

Just a few weeks ago the full committee met with a special panel of the National Academy of Sciences to receive a comprehensive report of the Nation's needs in basic research. Those of you who have read the report will recall the forecast of an expanded rôle for the National Science Foundation. You may also have noticed some observations concerning the shifting status and operations of other Federal agencies engaged in scientific and technological research.

I point this out in order to emphasize that during the period of the Foundation's lifetime, there have likewise been many changes in the dozen or so Federal departments or agencies active in the scientific

field. We will, therefore, be obliged to consider the relationship between these entities and the Foundation as well as focusing on the Foundation itself.

All in all, the task before us is broad and will require a good deal of time and concentration. This is a major challenge which the subcommittee faces.

I have already indicated my pleasure, Dr. Haworth, in your being with us today. We recognize the great effort that you have put into your work as Director of the National Science Foundation, and we are looking forward to your participation with us for the next few days.

Mr. Roush. May I echo what you have said, and also point out that Dr. Haworth has received at least three degrees from Indiana University, and is a product of the great midwestern section of this country. I am happy to see him honored in his present position as Director of the National Science Foundation.

Mr. Daddario. Thank you, Mr. Roush.

STATEMENT OF DR. LELAND J. HAWORTH, DIRECTOR, NATIONAL SCIENCE FOUNDATION

Dr. Haworth. Thank you Mr. Chairman and members of the committee.

I certainly appreciate this opportunity to appear before you and to try to tell us something about our current thinking, our programs, our plans, and so forth.

With your permission, Mr. Chairman, I would like to proceed along the following lines. I have a document which lies before you of about 20 pages. At the rate I read it would probably take 25 or 27 minutes to read. This document very, very briefly tells a history of the Foundation and the kind of programs it has in qualitative terms. It is not statistical, but I hope it will give a basic foundation for the discussions from that point on.

Having read this document, I would like to proceed to extemporaneous discussion using a set of charts, of which there are a good many. This will be a fairly lengthy process I am afraid.

Then, finally, I would like to end with a prepared statement, which is not yet finished, that will lay before you some of the things we forsee in the future, some of the problems we face, some of the possible changes in direction or perhaps changes in emphasis that we might make.

If that is satisfactory, I will proceed along those lines.

Mr. Daddario. That is most satisfactory, Dr. Haworth.

Dr. Haworth. Then, I will proceed, Mr. Chairman, to read the document that lies before you.

The past 15 years, which cover the span of the Foundation's existence, have been important years for science. They have been years marked by rapid advances in research and science education. It seems to me these hearings on the Foundation are most timely. The members of my staff and I stand ready to discuss our activities, to provide data, and to cooperate in whatever ways the committee sees fit in order to insure that these hearings are both productive and constructive.

Two recent reports stimulated by this committee provide background on the programs and many of the problems which have con-

cerned the Foundation during its history . The first, prepared by the National Academy of Sciences and entitled "Basic Research and National Goals," is directed at an understanding of the needs for and of an expanding science. The second, prepared by the Science Policy Division of the Legislative Reference Service of the Library of Congress, and entitled "The National Science Foundation—A General Review of Its First 15 Years," provides considerable detail on certain aspects of NSF's history and programs.

Mr. DADDARIO. I would like to add just one point here. In referring to these reports, I would like to call attention to the fact that you also have prepared for us a study on science education in schools in the United States. This covers both the elementary and secondary schools, and there is a followup report on graduate schools and colleges. I think these are also significant contributions to the point you are raising here.

Dr. HAWORTH. Thank you, Mr. Chairman.

The issues raised in these reports on the character of the Foundation's, and, more generally, the Government's participation in research are fundamental. They are related to a group of problems which I identified and discussed as having particular significance in the last annual report of the Foundation.

These reports record the growth of the Government's interest in science since World War II. I need merely to review a few salient statistics to indicate the extent of that growing interest. In fiscal year 1950, when the Foundation was created, the Federal agencies obligated approximately $1 billion for research and development, of which about $50 million was for basic research. In 1960, the total obligations for research and development were $7.5 billion, of which $600 million was the portion for basic research. Currently, in fiscal year 1965, the amounts are estimated at $15 and $1.9 billion, respectively.

These statistics would have little meaning if they could not be related to an increased tempo in science and to a qualitative improvement in the resulting output of the scientific effort. This relationship is not difficult to establish. One has but to recognize the postwar position of American research and to consider the recent achievements of our Nation's laboratories. All of the Federal agencies which conduct or support scientific activities have contributed to this upsurge.

The Federal Government—in this case the totality of all Federal science-supporting agencies—provides funds for science and technology in pursuit of three objectives, which I described as follows in the Foundation's annual report:

A first objective is to make sure that our capabilities in the areas of science and technology are the very best the social structure can produce. This means that leadership must see to it that we have a vigorous and healthy scientific and technological base which will lead to continued social and economic advance. Scientific and technological progress must be viewed as dependent, in the long run, on two factors:

1. The need to maintain and constantly augment a fund of scientific knowledge derived through research, particularly basic research.

2. The need to strengthen science education, especially higher education, to be sure that we produce adequate numbers of young scientists and engineers qualified to do the things our national goals require.

A second Government objective is to develop, or have developed, the hardware, materials, and processes required for national programs conducted by the Government itself, such as those in military defense and space.

A third Federal objective is to foster and encourage developments that will react to the direct benefit of the people. Here, the distinction lies in the fact that the public rather than the Government is the "customer." Improvements in public health; better practices in agriculture; improved transportation; development of energy, water, and other resources; and conservation: these and many other applications of the sciences are properly the concern of the Federal Government since private elements of our society cannot be expected to assume sole or even primary responsibility.

All agencies contribute in some respect to each of these objectives. The National Science Foundation is primarily associated with the first, where as the other Federal agencies are primarily concerned with one or both of the others. Thus the National Science Foundation's mission is general and may be described as "the advancement of science in the national interest." In its pursuit the Foundation endeavors to promote the national scientific and technologic capability by supporting the extension of scientific knowledge and the strengthening of the educational processes leading to such extension.

The role of the Foundation can be better understood if we identify its sphere of responsibility within the complex of activities that are popularly known as research and development. These activities cover a very broad range; they are usually divided into three categories: basic research, applied research, and development. The boundaries between them are not sharply defined, nor can they be neatly compartmented.

Basic research seeks an understanding of the laws of nature without regard for specific utilitarian value. The real objective of basic research is not merely to discover a collection of separate facts by weighing this and measuring that, but to develop an understanding of nature by seeking out the why and how of nature's behavior. Basic research is important in several senses: it has very great intellectual and cultural value, it is the foundation upon which rests all of our technological advances, it is intimately involved in the education and training of first-class scientists and engineers.

Applied research is carried out with practical and, usually, but not necessarily, specific objectives in mind. Such research may involve special measurements to yield data needed for some engineering purpose. It could be a broad study of high-temperature materials for application to many purposes. Much applied research seeks detailed information regarding a specific situation for which the general laws are known from basic research.

Development is the systematic use of knowledge directed toward the design and production of useful prototypes, materials, devices, systems, methods, or processes. This includes the construction and testing of "hardware," including military weapons systems, space vehicles, nuclear reactors, and many other items great and small. This is the costliest aspect of the research and development spectrum, both in Government and in private industry. It is distinct and separate from research in that it applies the results of research to the production of end products.

All three areas of activity are important. Applied research builds on the results of basic research. Development builds on both. The more complete our underlying knowledge, the easier the task of applied research and of development. In the broad sense, research is in this era the foundation upon which rests all technological develop-

ment; such development is harvested from knowledge resulting from a great many experiments and the understanding derived from them. It would be a misconception of these activities if one sought to divide a 1-to-1 causal relationship between a specific development and a specific piece of basic research.

The Foundation's principal sphere of responsibility within the research and development domain is basic research and science education. These are closely related. Basic research is the extension of knowledge, and science education—particularly at the higher levels—is a closely related element clearly essential to progress in science. Not only does the search for knowledge on the frontiers of science provide experience and cultivate the student's ingenuity and resourcefulness, but it also becomes a part of the teacher-student-disciple relationship which lends vigor to our cultural development.

The special character of NSF was given to it in its enabling act of 1950. Under this broad mandate fall responsibilities for the promotion of basic research and education in the sciences, and for the pursuit of national science policy. By that statute and later legislative action, the National Science Foundation is defined to be the National Science Board and the Director of the Foundation. The Director is a full [voting] member of the Board, is Chairman of its Executive Committee, and serves as the Foundation's chief executive officer.

The Board has broad responsibilities for providing policy guidance for the Foundation and for approving its actions. Over the years, the Board has provided NSF with leadership and has served science and the Nation well. Although the Board continues to review new programs and problems relating to grantmaking activities, it has in recent years given primary attention to major policy problems and national issues relating to science. The Board has delegated to the Director responsibility for making final decisions on those operations for which there exist well-defined models and rules, except for those relatively few cases where very substantial sums of money are involved.

The range of current Foundation programs is quite varied. Perhaps you will permit me to describe some of these after making a few remarks to provide historical perspective. As you all know, the Foundation was proposed in 1945 in the report of Vannevar Bush, Science, the Endless Frontier. During the period in which the Congress was considering the recommendations of that report, the Office of Naval Research, the National Institutes of Health, the Atomic Energy Commission, and other agencies established and supported vigorous research programs in relation to their own missions. An important component was support of research in universities. There were thus established ties between the Nation's universities and the several Federal agencies—ties which have been especially cultivated by the Foundation—and these relationships have proved to be so mutually beneficial that it is difficult to recall the time when they did not exist.

The first years of the Foundation were devoted principally to its own support activities. In the coordinate Foundation responsibility for the pursuit of science policy, early attention was given to statistical studies and analyses on national research and development investment and on questions related to scientific and engineering personnel.

In all the research programs, emphasis was placed on giving assistance to individual scientists of high creative ability. The technique of review of research proposals by panels of the proposing scientists' peers was established. The project method was adopted—after close scrutiny of alternatives—and has been found to have considerable merit for the Foundation. In the early days of minimal budgets, it provided a means for maximizing the immediate research return for the support dollar. The project grant is still the Foundation's major means of supporting research. Let me interject here that when I speak of research or science in this talk, I mean it to include not only the physical and biological sciences but also mathematics, engineering, and the social sciences.

The other major activity initiated in the Foundation's early days was the awarding of graduate fellowships. In accordance with the act, these awards were made to highly selected young men and women on the basis of ability and were open to all citizens. Today the Foundation awards a variety of fellowships for both students and teachers, ranging all the way from predoctoral students to senior scientists of established reputation.

These two activities—the support of basic research by means of project grants and the award of fellowships—remain as two of the major program activities of the Foundation, but over the years they have been supplemented by many new activities. Rather than present a chronology for these new efforts, I believe it would be of more value if I now discuss them as they are today.

In its support of research and science education, the Foundation has chosen, wisely, I believe, to continue to stress investment in people as a broad element of the strategic approach to helping science move forward. Science advances through the creative efforts of well-educated, gifted people. Identification of such people and appropriate support for their endeavors constitute a logical approach to assuring that progress will indeed take place. This investment is made primarily through the country's institutions of higher learning by—

(1) Support for high-quality research at a level which encourages necessary growth in the research activities of academic institutions;

(2) Support for individual and cooperative programs to increase research emphasis on scientific areas of national interest, such as oceanography and the atmospheric sciences;

(3) Promoting the attainment of higher quality in science education;

(4) Measures to attract sufficient numbers of talented students to undertake careers in science, and to encourage the achievement of excellence by individuals; and

(5) Efforts to stimulate the growth of existing centers of scientific excellence and encourage new centers wherever this is feasible.

As I have stated, our major mechanism for supporting research today, as in 1951, is the project grant given in response to individual proposals and not fitted into any particular pattern. However, the Foundation's programs have become more varied and now include certain especially identified, concerted efforts.

The first group is a class of so-called national research programs, usually of an interdisciplinary nature, which are conducted in pur-

suit of concerted national or scientific goals and which pose special problems—problems which may relate to geography, funding, equipment, manpower, or simply magnitude of effort. They are normally supported by means of project grants, as in our regular research support activity, but are given identity and emphasis by means of the selection and collection of research support into concerted programs.

NSF's first venture in this direction was in the role of providing support—on behalf of the entire Government—for the International Geophysical Year. With advice from the National Academy of Sciences and special funds provided by the Congress, this program was launched as part of a carefully coordinated, worldwide research effort designed to provide a fuller understanding of the earth and its environment. Geophysicists and others are still analyzing and working with the vast store of scientific information which was obtained during that intensive period of observation.

A current example is the support being provided for the Antarctic research program where NSF both coordinates and funds the U.S. component of the international scientific activities on and near the south polar continent. Logistic support is provided by the Department of Defense, and the Department of State serves in dealing with the international aspects of the program.

Another novel endeavor is the large-scale experiment to pierce the earth's crust by drilling through the ocean's floor, Project Mohole. The immense scientific potentialities of this enterprise have at times been somewhat obscured by the new and exciting technological aspects it presents. Despite its being fraught with technical difficulties which challenge our most advanced engineering capabilities, the project is worthy of man's imagination and creative endeavor—and of Government support. This project, which at present is in the stage of developing facilities, has some of the characteristics of NSF's national research centers which I will describe shortly, except that in this case—if I may make a pun—when the platform is operational it will be a sort of "roving center."

In addition to supporting the conduct of research, the Foundation also grants funds to universities and other research institutions for highly specialized—sometimes unique—research facilities, as well as major items of research equipment, such as nuclear accelerators, oceanographic vessels and shore facilities, specialized biological laboratories, and large laboratory equipment. The absence or inadequacy of facilities and equipment at many institutions is a key limiting factor in the advancement of research, and the resources of most institutions are inadequate to acquire the needed facilities without Federal assistance. The provision of the essential tools of research serves to make research scientists more productive and often makes possible investigations which could not otherwise be carried out.

In certain fields there is need for research facilities which are so expensive in money and effort that they can be afforded only singly or in very small numbers, but which should be available for use by scientists from many institutions. To meet this, and in some instances other needs, the Foundation has established and supports national research centers. For example, in the late 1950's it became apparent that progress in astronomical research was being limited in this country by the relative scarcity—and in some cases the unavailability—

of major observing facilities. Aware of this problem, the Foundation set up special mechanisms to study possible solutions and as a result of careful consideration decided to establish national observatories patterned in concept after certain of the national laboratories of the Atomic Energy Commission. Today there exist two national astronomical observatories in the United States: the National Radio Astronomy Observatory at Green Bank, W. Va., and the Kitt Peak National Observatory in Arizona in the optical field. So that American astronomers may have a facility for observing the parts of the universe which are visible only from the Southern Hemisphere, a third national astronomical facility, the Cerre Tololo Observatory, is being funded by NSF in the Chilean mountains of South America.

Another center is the National Center for Atmospheric Research at Boulder, Colo., which is in response to the need for a concerted attack by many scientists on problems of the atmosphere as well as to the need for centralized facilities and services. It operates balloon and aircraft facilities and provides specialized equipment. These national centers provide modern facilities for use by significant numbers of visiting university scientists and by graduate students, as well as regular permanent staff, and thus constitute effective extensions of university research activities. They are operated for the Foundation under contract with nonprofit corporations sponsored by groups of universities.

Just as new activities have been introduced for the support of research, new mechanisms have been developed to enable the Foundation to discharge more fully its responsibility for science education. We are interested in improving such education at every level, from primary school, through postdoctoral study, and even to the further learning which senior scientists need in order to maintain their creativity. Generally speaking, the various programs have three objectives: to assist qualified individuals to obtain additional advanced training or partake in additional activities, to improve the quality of material that is taught and the methods that are used in teaching it, and to improve the knowledge and other qualifications of the teachers. Let me now discuss briefly some of our efforts in these areas.

I have previously mentioned the various kinds of fellowships which the Foundation now offers to individuals. These include a continuation of the Foundation's original graduate fellowship program, an activity which has been and is regarded as one of our most effective efforts; the awards in this case are made directly to students on the basis of merit in open national competition. Our cooperative graduate fellowships were introduced in 1958 and are awarded to graduate students who apply through the universities which they attend. We have two postdoctoral fellowship programs which provide for advanced training and study for especially able individuals who wish to become still more effective as investigators. Our science faculty fellowships provide support to university and college science teachers for study and work to meet their individual needs, with the primary aim of making them more effective teachers of undergraduate students.

A complementary activity is the support of graduate trainees. The objective of this program is to increase the number of qualified individuals working toward advanced degrees by more fully utilizing

graduate training facilities throughout the Nation. To achieve this the trainees are supported through grants given to universities which can accommodate increased numbers of graduate students who are selected by the grantee institution.

At the undergraduate level a program has been designed which provides opportunities for undergraduates to participate in significant research under the guidance of senior scientists. The number of such undergraduate research participants is about 6,200 annually. Some 37,000 students have been supported since the program's initiation.

A closely related activity is the effort to provide colleges and universities with undergraduate instructional equipment. Here, we match funds with the institution to assist in the purchase of much-needed equipment to provide adequate laboratory training for undergraduates. This equipment support activity has had a widespread influence throughout the Nation and has helped a large number of small colleges as well as the institutions that train most of our undergraduate majors in science. About 950 grants are given each year to some 530 institutions.

A special activity which has a multiplier effect is our 12-year-old "institutes" program which seeks to upgrade the teachers of science. Institutes are group training activities in science, mathematics, and engineering for teachers of these subjects from the elementary to the undergraduate level with special emphasis so far on the secondary schools. These activities are organized and conducted by several hundred universities and colleges. Institutes are conducted in the summer, and during the school year for inservice teachers. A smaller number of so-called academic year institutes give training to teachers who have taken a leave of absence for a year. Stipends are given to teachers enrolled in the summer and the academic year institutes.

Funds provided by the National Science Foundation this year will make it possible for more than 42,000 teachers to obtain subject matter training which makes them better teachers. Since these activities were initiated about 300,000 such teacher trainee opportunities have been provided. However, the number of individuals affected is considerably smaller since many teachers have partaken in more than one institute. Incidentally, activities of the institute type are now being employed by the Office of Education mainly in nonscience fields.

A most unusual—and successful—activity is that for course content improvement. Grants are made to outstanding scientists and teachers to work together to modernize and improve the content of science courses at both the precollege and the undergraduate levels. These groups have incorporated the latest scientific ideas into texbooks used in lectures and laboratory classrooms, and equipment used to demonstrate the principles of science.

Because of our science education programs have been designed to help solve a number of problems, the Foundation currently supports quite a few other educationally oriented activities. I want to emphasize that our concern in science education is directed primarily at the qualitative aspects—at intensifying the experience and making more effective the work of students and teachers undergoing science training. We are involved in experiments and innovations to improve the learning process—and we intend to continue to stress the role of NSF

as a trailbreaker in this area. In our discussions a bit later we can deal with some of those other elements.

Let me turn now to another important set of activities, each of which supports both research and science education. Here I refer to our direct support of academic institutions, primarily universities, in order to strengthen their research and science education capabilities.

To meet the critical need for graduate laboratory facilities, the Foundation undertakes to match funds for such items as the construction of new—or the renovation of existing—research laboratories and the acquisition of apparatus required for advanced training and research projects. More than 100 grants for such purposes are now being given each year.

For the past 5 years (under a separate program), support has been given to educational institutions in the form of institutional base grants—an annual grant of funds based on a tapered formula related to the research support which these institutions receive from the Foundation. The tapering is such as relatively to favor those institutions receiving the least support. Under present policy grants range in size from small amounts to a maximum of $150,000. These institutional base grants may be used for any purpose which directly supports academic science, and thus provide funds for such items as rental costs for general use computers, equiping shops, library acquisitions, student stipends, and many other purposes. This type of support provides a highly desirable and helpful degree of flexibility to universities and colleges, thus overcoming to some extent certain difficulties inherent in the project grant system which I shall discuss later.

The Foundation's newest technique of institutional support is the science development grant. Hereby means of grants of a few million dollars each, NSF is seeking to increase the number of outstanding educational institutions and to accelerate the development of schools of known quality and acknowledged potential. Proposals for such grants must be built upon well-developed plans to produce substantial upgrading in the quality of some significant segment of the institution's science activities. Grants of 3-year duration are made to institutions judged to have the greatest potential for moving upward to and maintaining a high level of scientific quality. We have spent a great deal of time in clarifying the goals and selecting criteria for this program. We recently announced the first four science development grants to the University of Oregon, Washington University in St. Louis, and Western Reserve University and the Case Institute of Technology in Cleveland, Ohio, the last two being in accordance with closely coordinated plans. We hope to award several more grants shortly.

The Foundation has a special responsibility for fostering activities to assure widespread dissemination and effective utilization of research findings. Moreover, our science information program is one of the areas in which the Foundation has been authorized by Congress to extend its support beyond basic research. NSF's science information programs do not involve large expenditures, but they are broad in impact; they include support of activities in basic research, applied research and testing, all directed at improving the methods of disseminating science information, as well as a number of activities

designed to assure effective dissemination to U.S. scientists of research results, no matter where in the world they have been achieved and no matter in what language they were published.

Two activities deserve special mention. The first is the wide support provided for the translation and dissemination of foreign science information. Grants are made to scientific societies to select, translate, and publish the research appearing in the foreign scientific literature in the field of their interest. In addition contracts have been made with organizations in Poland, Israel, and Yugoslavia for the regular translation of books and periodicals from Russian into English. Payment for these services is made in counterpart currencies.

The second is a developmental program, jointly funded by NIH, DOD, and NSF, aimed at providing a much-needed, high-speed source of chemical information for scientists. The project will establish a computer-based registry system for chemical compounds which will ultimately serve chemists throughout the Nation. The program is a pioneering effort in Government interagency coordination in the information systems field.

To this point I have been discussing NSF activities in support of science. Through such efforts, we make available more than 95 percent of our annual appropriation to advance scientific knowledge and to build our strength in science education. I now turn to a rather different function.

The original act authorized and directed the Foundation to develop and encourage the pursuit of a national policy for the promotion of basic research and education in the sciences. Pursuant to this obligation the Foundation early in its life engaged in a program of gathering statistics with respect to scientific manpower and basic research. These data, most of which had not previously existed, have provided an ever-increasing base upon which to study problems related to national science policies. In carrying out its policy function, the Foundation has issued reports, such as "Basic Research a National Resource" (1957), "Government-University Relationships in Federally Supported Scientific Research and Development" (1958), and "Investing in Scientific Progress" (1961), which attempt to place the growing needs of science in perspective.

By Reorganization Plan No. 2, in 1962 there was transferred to the Director of the newly established Office of Science and Technology so much of the Foundation's policy function as is necessary to enable that official to advise and assist the President in achieving coordinated Federal policies for the promotion of basic research and education in the sciences.

I might interject, Mr. Chairman, that a committee of the National Science Board gave considerable advice to the executive branch that led to this reorganization plan. There was a study by a special committee of the Board.

At the same time the President stated that the Foundation would continue to originate policy proposals and recommendations concerning the support of basic research and education in the sciences, and that the Office of Science and Technology would look to the Foundation to provide studies and information on which sound national policies in science and technology could be based. The Foundation has, therefore, not only put a great deal of effort into serving the needs

of the Office of Science and Technology and the Federal Council for Science and Technology, but has also continued to consider and make recommendations, when appropriate, on policy matters; in order to accomplish these ends, it has also expanded its factfinding and analysis function, and has recently given this function a greatly enhanced organizational position. Now that we have gathered and have at hand a more nearly adequate base of information, we believe we can launch a major effort to isolate particular roadblocks and problems in the path of the Nation's scientific development—and thus assist more effectively in the development of policies to assure healthy scientific progress for the country.

This necessarily incomplete discussion has, I hope, given some idea of the scope and general nature of our activities. The administration of these activities has been assigned to senior members of the staff who have been instructed—in line with the policy of the President to improve efficiency by eliminating needless and bureaucratic practices—to seek simple and effective means for strengthening the Foundation's programs. I believe we are effectively implementing this policy.

With your permission, I should now like to present and discuss some visual materials which I believe will help to convey the current status of the Foundation, its place among the several Federal science agencies, and the size and scope of its current activities.

Mr. Daddario. Go right ahead, please.

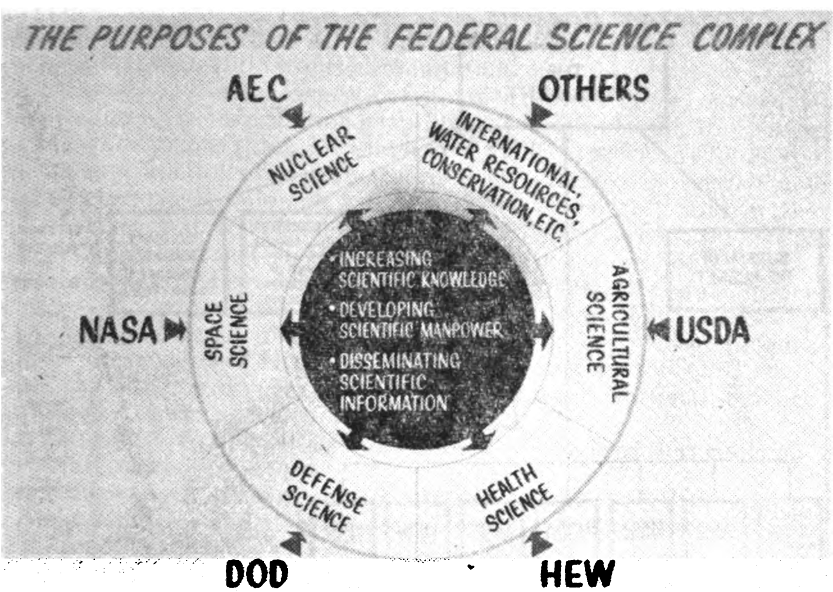

Chart 2

Dr. Haworth. I would like first to discuss very briefly the content of chart 2, "The Purposes of the Federal Science Complex." I note in the prepared text the way in which basic research and applied research are the underpinning for all the practical applications in

science. I am speaking here of the practical rather than of the cultural aspects. This chart is an attempt to diagram the relationship of basic science to the practical objectives of the various agencies.

The central part of this diagram represents the sources, the wellsprings of our advance in science, and it is, of course, in this area of increasing scientific knowledge, of developing manpower, and of helping to disseminate information that the Science Foundation works.

Now, many other agencies work in this area, too; in fact, all of the technical agencies do. All of the agencies support basic research. All of them, directly or indirectly, have an impact on developing scientific manpower.

The underlying—and perhaps I should define "underlying" in such a way as to include at least some elements of applied research—the underlying activities in the center of the diagram impact outward and are useful in all the more specific applied and developmental areas, such as space, defense, the nuclear sciences, and so forth, where the agencies indicated around the edge of the circle are particularly concerned. So, this is meant to show that there is a complete interrelationship between parts of this complex. The inner portion represents the basic underpinnings; the outer sections represent the applications, and the agencies shown are those particularly interested in the applications, although every one of these agencies also finds itself within this inner circle.

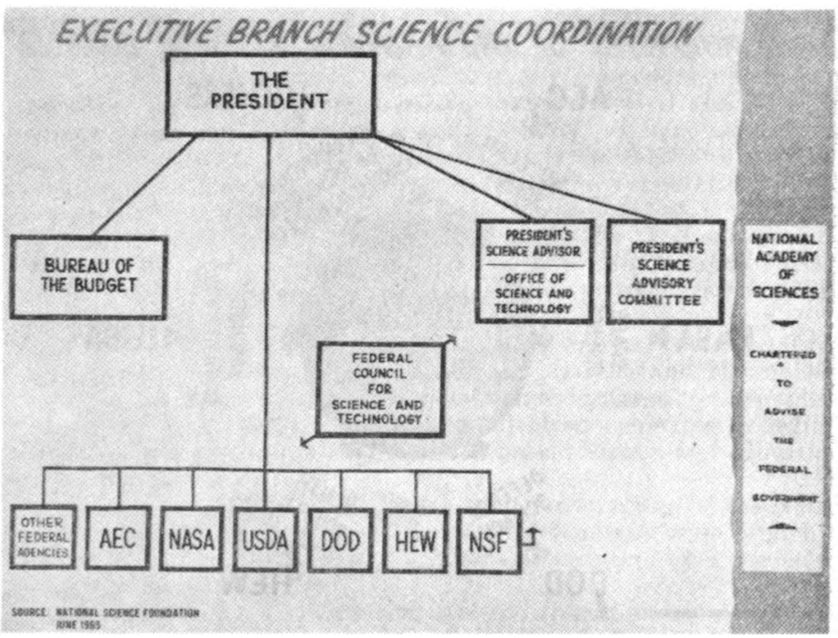

CHART 3

Chart 3, "Executive Branch Science Coordination," is a crude indication of the relationship within the executive branch of the activities of the various agencies. All, of course, report to the President.

The President is served on the one hand by the Bureau of the Budget and on the other by the President's science adviser, who is also the Director of OST. The President is also advised by the President's Science Advisory Committee, of which traditionally the science adviser is the Chairman.

In addition there is the Federal Council for Science and Technology, made up of a single representative from each one of the agencies primarily concerned with science or technology, that is with research and development. The Council is also chaired by the science adviser. This Council serves as the coordinating body for the whole group of agencies, not only among themselves but with the White House. It is concerned with both the formulation and suggestion of policy and also the coordination of particular programs. It has many subpanels on such subjects as oceanography, planetary sciences, science information, and so forth.

The arrow leading up from NSF is meant to indicate that NSF has by statute a special role over and above the other agencies with respect to collecting the kind of information that I spoke of earlier and suggesting policy. This simply means that NSF feeds back to the executive offices, the FCST, et cetera, the results of its studies and the suggestions that it has.

Mr. Daddario. Do you mean that at the time the policy function referred to under the Reorganization Plan No. 2 was transferred to OST, some of it was retained by the National Science Foundation?

Dr. Haworth. That is right.

Mr. Daddario. So, there is an interrelationship, although it is not now a prime responsibility of the Foundation.

Dr. Haworth. Certain aspects of it are still, in a sense, our prime responsibility—the information gathering, for example, the Manpower Register, and various things of that sort. NSF never was assigned the coordinating function even in the original act. Let us say the primary initiative for the development of policy is, of course, now in the Office of Science and Technology. Originally, NSF was supposed to study and encourage—I don't remember the exact words of the act—national science policy, which includes, of course, Federal science policy, but that part of the original NSF assignment that is necessary for OST to advise the President on what kinds of Federal policies ought to be developed has now been transferred to the OST. Of course, the OST didn't exist when the original National Science Foundation Act was passed.

Mr. Daddario. Could we say that, in a sense, a little of that responsibility is left over?

Dr. Haworth. A little of that is left over. There is both the question of how much—and it is somewhat intangible I have to admit—is an assigned responsibility in the legal sense, in the formal sense, and how much takes place just by tradition and relationships and so forth. I think it is fair to say that OST, Dr. Hornig and his office, look unusually strongly to the NSF for assistance in helping them develop information and policy both for OST and for the Federal Council; so, we are simply more engaged in this than are other agencies.

Mr. Miller. Isn't that brought about, too, by reason of the fact that most of the other agencies—AEC, NASA, Agriculture, Defense,

HEW—have fairly specific missions and the Foundation must come in and fill the gap between these missions?

Dr. HAWORTH. That is right, and that, of course, was the reason for the original provision in the act, at least I so assume.

Mr. CONABLE. Would you still stand by this chart putting NSF down the line from the other agencies when it has a coordinating function in gathering information for the other agencies?

Dr. HAWORTH. NSF has two roles: it is an operating agency, it supports research, it has national centers, it supports research in the universities, and so on; just like the other agencies do.

It also has this somewhat special responsibility for assisting in the collection of pertinent information, for making analytical studies, and for making suggestions with respect to policy. That is what I meant to indicate by this arrow. NSF wears two hats; that is about as good a way of saying it as any.

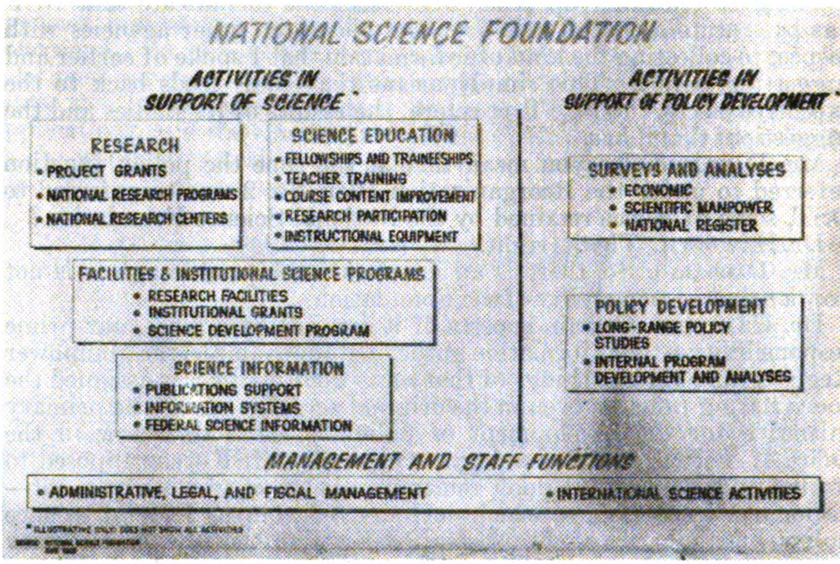

CHART 1

I would like to call your attention now to chart 1, "National Science Foundation Activities in Support of Science and Science Policy Development." This simply shows in highly schematic form the various activities of the Foundation, nearly all of which are outlined in the prepared statement:

> Research, which, as I said, is carried out through project grants, national research programs, and national research centers;
>
> The various science education activities, which are somewhat condensed here;
>
> The support of institutions; that is, the support that isn't in the form of project grants for the conduct of research but rather for other things such as laboratories, institutional base grants, and the science development program; and

Science information, which is important to research, to the progress of research, but is not, except in the sense of research on information processes themselves, in itself research. Rather, it is seeing that appropriate use is made of the results of research.

Then, there are the surveys and analyses that I spoke of, the policy development activities, which, of course, have to include development of our own policies and programs as well as the broader responsibility that we were speaking about a few minutes before.

Then, cutting across the whole thing, there are our own management and staff functions, which include the usual administrative activities of any agency.

We are involved to some extent in international activities, which thread through these other programs. We have a staff office that coordinates those international activities in which we are engaged but doesn't itself support them, the support coming from the science programs.

We can leave chart 1 out all the time and refer back to it from time to time as I come to various parts of the program.

Mr. DADDARIO. Dr. Haworth, on your chart you refer to fellowships, and on page 13 of your statement you talk about them in reference to their being based on merit in open national competition. Yet, there are limitations geographically, are there not?

Dr. HAWORTH. Yes.

Mr. DADDARIO. If there are, how does that work harmoniously with the idea of their being based on merit in open national competition?

Dr. HAWORTH. By the fact that from the beginning the Foundation was empowered and directed by the act to provide fellowships with the following instructions:

(1) The individuals would be chosen on the basis of merit;

(2) They would be free to go to the institution of their choice; and

(3) That other things being equal, one should take into account geographic distribution.

I don't remember the exact words, but, in effect, the act says that if two or more applicants are judged to be equal in merit, and you cannot give a fellowship to all because of limitation on funds, then you should choose the one or ones who would help to give a wide geographical distribution.

The way that is handled in the so-called graduate fellowship program, which was the first NSF fellowship program, is that the applicants are placed in what are called quality groups. Group 1 is judged to be the highest ability individuals; group 2 the next, and of substantially equal ability; and so forth.

Obviously, this is a subjective thing in many ways. First, fellowships are given to all the people in group 1. Group 1 is chosen to be small enough so that this can be done. Then, say, there are not enough available fellowships to cover all the people in group 2. You select those in a way to achieve a reasonable geographic distribution.

Mr. DADDARIO. Do you think that even though there is that barrier to being just on merit alone, it does work out properly, and it does achieve its objectives?

Dr. HAWORTH. Yes; I think so. In principle it is not a barrier because you are selecting from among a group judged to be of substantially equal ability. Instead of flipping a coin to break ties, you note that several people in group 1 from this State and that State have received fellowships, but only a few individuals from some other States have received any. Your first awards from group 2 then would be made to individuals from "deficient States."

Mr. DADDARIO. Congress is adding to the barrier, as I put it, by imposing a percentage limitation, is it not?

Dr. HAWORTH. The House appropriation bill this year did; yes.

Mr. DADDARIO. Is it an inhibiting factor to getting the type of quality that you would like to have?

Dr. HAWORTH. That would be a barrier. We would be forced to give some fellowships to people who were in a lower quality group than others who did not get them.

Mr. DADDARIO. Rather than in the method of balance that you have achieved up to this point?

Dr. HAWORTH. For example, Mr. Chairman, this year in quality group 2—I am speaking now of this graduate fellowship program, which is our blue ribbon fellowship program—there were about—if I remember rightly—650 people in it, but we had funds to support only 330 people in this quality group. Among those 650, there were 96 who listed New York State as their State of permanent residence. Now, if you selected at random, you would expect that half of these 96 from New York State in quality group 2 would have received fellowships, if we had disregarded considerations of geography. As it was, in this year's competition we were unable to make a single award to a New York State resident from quality group 2. Under the restriction of the House bill, we would have had to cut back the awards to New Yorkers even more. We would have had to reduce the number of awards to New Yorkers in quality group 1 by about 37 percent and we would have had to award these fellowships to residents of other States who had been judged to be in a lower quality group.

Mr. MOSHER. When you are talking about geographic distribution, are you talking about the residences of the people?

Dr. HAWORTH. I am speaking on the basis of what the people declare their residence to be.

Mr. MOSHER. Rather than the campus on which they do their work?

Dr. HAWORTH. Rather than the campus. The act is very explicit on that. They are permitted to go to the university of their choice. I am speaking now in terms of a State of permanent residence, although this is kind of fuzzy, because, as you know, many students, especially by the time they become graduate students, declare their residence to be wherever they are going to school.

Mr. CONABLE. Under the new bill there would be no New York students because they are so many New Yorkers in group 1?

Dr. HAWORTH. That is right. New York has about 10 percent of the population. A bigger than average fraction go to college. As a matter of fact, the number we have traditionally given in New York State, or any other State, is very closely proportional to how many residents of that State are in graduate school, how many graduates

in that State are getting Ph. D.'s, and so forth. There is a remarkable uniformity in that respect.

For example, about 17 percent of the graduate students in science and engineering in the United States say they are residents of New York State. Well, we gave about 15 percent of the graduate fellowships to residents of New York State.

Mr. DADDARIO. I imagine California would be similarly affected as New York in the near future?

Dr. HAWORTH. Yes, but not by such an amount. At the moment they do not have as large a fraction as New York State. If any limit was set, it would affect them but in a more limited way compared to New York State.

Mr. MOSHER. Actually, these New Yorkers would be spread over a large geographic territory in the location of their campuses?

Dr. HAWORTH. Yes and no. The graduate fellowship holders tend to concentrate in a relatively few universities. That is where the real concentration is, in their choice of where to go, and they choose to go to Harvard, MIT, Chicago, Stanford, and so on. But the thing that one must remember about all of this is that what really counts is where they go afterward. These universities are not local universities, they are national universities. For example, in the freshman class at MIT, only 11 percent of the students come from the State of Massachusetts—the remainder come from all over the country. By the time they get to be seniors about 20 percent of them say they live in Massachusetts, but this is just because they changed their State of residence. After they graduate they fan out to many graduate schools, of course, and after they get their advanced degrees, that is, those who do, then they fan out all over the country. There are people who study at MIT from every State in the Union. So, we have to think of the matter in this way.

The thing I fully agree we must do—and it will apply not only to fellowships, particularly, but also to the whole situation—is we must be sure, as best we can, that a bright youngster from one part of the country has just as good a chance to climb up the ladder as a youngster from any other part of the country. That is the real problem.

Part of the trouble is that there could be two people of equal potential, say, one in New York State and one in some other part of the country without as good an educational system. The one from New York State gets good training through elementary and high school and undergraduate school—gets better training than the other fellow—so he just naturally has a better chance in a national competition, not because he is intrinsically any better, but because his background is better.

Mr. MILLER. Isn't that our big problem today. We must try to raise the standards of primary and secondary education to wipe out these deserts?

Dr. HAWORTH. Yes, I think that is the big problem up through college, but we should meet it by lifting the standards——

Mr. MILLER. Not by leveling them off.

Dr. HAWORTH. Not by leveling off. By lifting, not by bulldozing.

Mr. CONABLE. Not by penalizing New York.

Dr. HAWORTH. That is right.

So, we will just leave chart 1 here, and I will undoubtedly refer to it from time to time.

Next, I thought it might be worthwhile to give the total national picture and the total Federal picture in order to fit NSF into context. Some of these are things I said to you nearly 2 years ago, but I think that to have them freshly in mind might be worthwhile. I will speak more briefly than I did at that time when I gave a more general presentation.

First, let's look at chart 4, "Funds Used for Research, Development, and R. & D. Plant, by Source of Funds, 1963." I will take up funding for research and development in the national sense now, not just Federal funding, but the total funding, and come to education later. Unfortunately, calendar year 1963 is the last year for which we have sufficiently detailed data because we have to get reports from outside the Government as well as inside to be able to give you total figures.

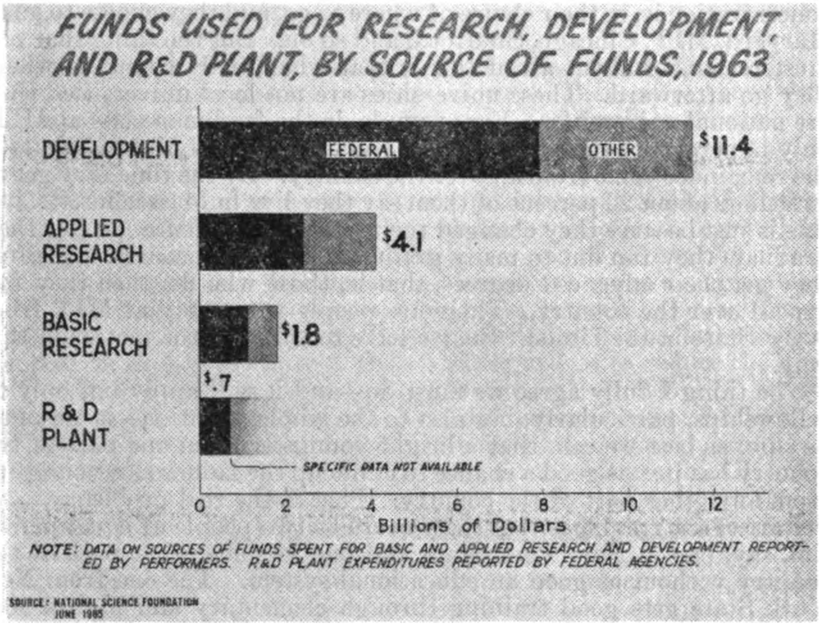

CHART 4

In 1963, for research and development, and R. & D. plant, something more than $17 billion was spent. Now, we can't be precise about it because we do not have figures from industry, for example, on their expenditures for R. & D. plant. In many cases companies do not know themselves, because when they build a building, it may be partly for R. & D. and partly for something else, and it is pretty hard to pro rate the cost.

If you include everything spent for development, and for applied and basic research, then the Government component for R. & D. is some $11.4 billion. In addition, Federal obligations for R. & D. plant were $7 billion. There is an undetermined amount for R. & D. plant from industry and universities.

As you can see, the solid part shows the Federal share of each component, and the cross-hatched part, the outlays, by the others, primarily industry, secondarily the universities.

Of course, development is carried on primarily by industry. Federal financing of development is just under $8 billion, and all other financing, around $3½ billion. Thus, of the $11.4 billion for development, the Federal Government is funding a little less than 70 percent.

There is a total of $4.1 billion for applied research. Admittedly the boundary lines between development, applied research, and basic research are very, very fuzzy. I don't know how to say sharply this is applied research and this is basic research, and I don't think anyone else does. You give the best definitions you can, and respondents classify their activities for NSF surveys as well as they can. In the field of applied research the Federal Government is supplying about 60 percent, a little smaller fraction than for development.

In basic research the Federal Government is supporting $1.1 billion out of $1.8 billion, which would be a bit over 60 percent.

It is interesting that in development the Federal Government provides a bigger fraction than in applied research and basic research.

RESEARCH AND DEVELOPMENT, 1963

Intersectoral Transfers of Funds Used for Performance (Preliminary)

(Millions of Dollars)

NOTE: Data are Based on Reports by Performers

Source: National Science Foundation, 1964

CHART 5

Chart 5, "Research and Development, 1963," shows on the one hand where funds originate and on the other where they are used. For example, the top line shows that of the total spent for research and development in 1963, the Federal Government provided $11.34 billion. Of that around $2.4 billion was spent in-house; $7.34 billion was spent by industry; $0.775 billion by the colleges and universities proper—and you are familiar with what I mean by that—$0.525 billion in the Federal contract research centers at universities, such as Los Alamos,

Jet Propulsion Laboratory, and so on; and \$0.3 billion by other non-profit institutions. It can be seen that the Federal Government provided about 65 percent of the total spent on research and development. R. & D. plant is not included in the data.

Let me break down one column here, the universities proper, because I am going to emphasize considerably the universities and colleges. In that year they spent an estimated \$1.175 billion on research and development—nearly all research, of course. Although an appreciable component was applied research, very little was development. The Federal Government provided an estimated \$0.775 billion of the total; industry provided \$0.065 billion through gifts or grants or contracts. The colleges and universities themselves provided about \$0.26 billion, which was about 22 percent of the total, and the rest came from foundations and other private sources.

This \$0.26 billion, of course, includes other public funds, because both the direct and indirect support given by State or local governments to research in colleges and universities is included in that line. The \$0.775 billion is only the contribution of the Federal Government.

I would like to credit the staff member who, some time ago, devised this way of displaying the data. I think it is a very useful form of presentation—a snapshot picture in certain dimensions.

Mr. MILLER. Dr. Haworth, the chart shows that about two-thirds of the funds used by the colleges and universities came from the Federal Government.

Dr. HAWORTH. For the support of research; yes. That is right.

Mr. MILLER. The Federal Government put up about 75 percent of the money, the States, apparently about \$0.26 billion, and the——

Dr. HAWORTH. The States and the private sources.

Mr. MILLER. The private sources?

Dr. HAWORTH. The endowments and so on of the private universities.

Mr. MILLER. Still, the burden of it is on the Federal Government?

Dr. HAWORTH. That is right.

Now, I should hasten to say that one thing that in my opinion does not completely show here is the many hidden costs that just do not get on the books. I don't mean just overhead costs, but all sorts of unrecorded costs. So, I think it would be fair to say that roughly a quarter of the funds for university-performed research is provided by the universities themselves, including public support and private support.

Mr. MILLER. Substantially all of the facilities are provided by the colleges and the universities?

Dr. HAWORTH. That is right.

Mr. MILLER. They cannot be evaluated?

Dr. HAWORTH. That is right. Those facilities have been built up over the years, of course. This is one of the very important things. If the universities hadn't been there and hadn't built up their facilities and their faculties, and so forth, we wouldn't have this resource to turn to.

Chart 6, "Trends in Federal Obligations for Basic and Applied Research, Development and R. & D. Plant," shows some of the trends in our Federal R. & D., from fiscal years 1956 to 1965. The top line

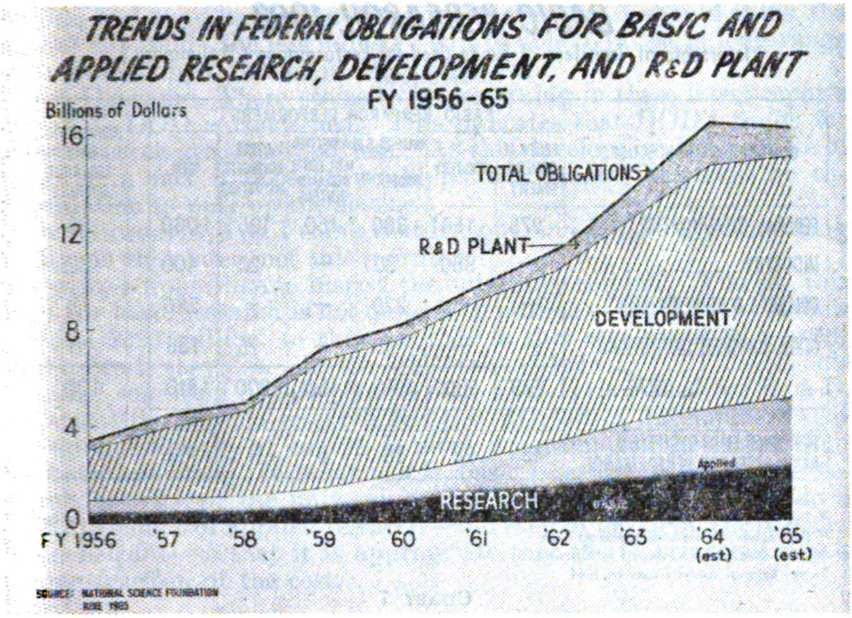

CHART 6

represents the overall Federal total as it has grown over the years, with corresponding trends for the components. You can see, as you well know, that the Federal research, development, and R. & D. plant total has grown very substantially over the last decade, but that there is a little tendency to level off in the last couple of years. The R. & D. plant total has perhaps leveled a little more than anything else.

We have indicated that you cannot sharply separate basic and applied research. The distinction is fuzzy. If you take the figures that have been collected—these are Federal agency estimates for 1964 and 1965—about 12 percent of the total is currently for basic research, 20 percent for applied research, 62 percent for development, and 6 percent for R. & D. plant. Thus, roughly two-thirds of the total is development.

I should hasten to say that these are estimates for fiscal year 1965. I should also point out that these are obligations and not expenditures. As a matter of fact, the expenditure line related to a rising obligations curve always lags behind the obligations. Thus, if you drew the expenditure trend line on this Federal obligations chart, the line would remain below the obligation total except in the earlier years. In other words, expenditures run about a billion dollars less than the obligations for most of the 1956–65 reporting period.

Let me turn to the component, basic research, because basic research is what the Foundation is authorized and directed to do as a primary obligation. Again, recognizing the fuzziness in the line between basic and applied research, we will look at a transfer table of the sources of funds used for the performance of basic research. Chart 7, "Basic Research, 1963," is such a table.

BASIC RESEARCH, 1963

Intersectoral Transfers of Funds Used for Performance (Preliminary)

(Millions of Dollars)

SOURCES OF FUNDS USED	BASIC RESEARCH PERFORMERS: FEDERAL GOVERNMENT	INDUSTRY	COLLEGES & UNIVERSITIES: PROPER a/	COLLEGES & UNIVERSITIES: FED'L CONTR. RESEARCH CENTERS	OTHER NONPROFIT INSTITUTIONS	TOTAL	PERCENT DISTRIBUTION, BASIC RESEARCH SOURCES

b/ This Amount Includes Funds from the Federal Government for Research Centers Administered by Organizations Under Contract with Federal Agencies

c/ Data Include State and Local Government Funds

NOTE: Data are Based on Reports by Performers

Source: National Science Foundation, 1964

CHART 7

In 1963 the country spent about $1.8 billion doing basic research. Of this a bit over a billion, or 58 percent, was provided by the Federal Government, 22 percent by industry, 12 percent by the colleges and universities, 8 percent from the private foundations, and so forth. Again, in the colleges and universities line are included public funds from State and local governments which were spent on basic research.

Of the basic research, the colleges and the universities proper perform not quite 40 percent. Now, here I think one has to say that there is probably a slant to this in the final sense. I believe, with no criticism to anyone, that basic research in the universities is likely to be more basic on the whole than basic research in industry. I do not mean that industry slants its reporting or that the universities slant it, but in the spectrum from the purest research where no one can foresee any possible application, up to work that is almost applied research, industry tends to concentrate more at one end of that spectrum and the universities more at the other end of the spectrum. So, it is a matter of the distribution within basic research rather than any sharpened difference in definition. In reality I think one would say that it is probably true that the universities do a somewhat larger fraction of "pure" basic research than the data would indicate.

Mr. DADDARIO. In that regard, industry being under the compulsion to control its funds, even within the area of basic research, do you see any trends in that direction? Will the Federal Government also exercise a more controlling element to its expenditures for basic research?

Dr. HAWORTH. I do not think, Mr. Chairman, I will venture to predict. I would say it would be a natural thing to do.

It would be a natural thing, for example, for the mission-oriented agencies to do as well for industry. They have to think about getting

results, and they have immediate problems. So, I should think the tighter the funds, the less industry will be able to invest in long-range intangible things, if that is what you mean.

Mr. DADDARIO. There seems to be something in these latest reports as far as DOD is concerned. This indicates that DOD's funds for basic research are somewhat less. As this develops over the course of time, if in fact it does, it would place a greater emphasis on the Foundation to pick up the slack.

Dr. HAWORTH. Yes, I think that is right, and I will have something to say on that later, not this morning.

Again, I would like to inspect the university column. You see, this total for basic research is not quite $700 million. Of this, the schools provide $220 million, so they provide in this case about 32 percent of the funds they use. In the other table (chart 5) p. 21 the schools supplied somthing like 22 percent of the funds they used for R. & D.

Part of the applied research and the little bit of development that the universities do, of course, is more programmatic in nature than the basic research. In other words, basic research is the natural research activity of the universities, but the universities proper do a certain amount of applied research—and even of development in order to be helpful—so that it is appropriate that the Government pay a bigger fraction of the cost.

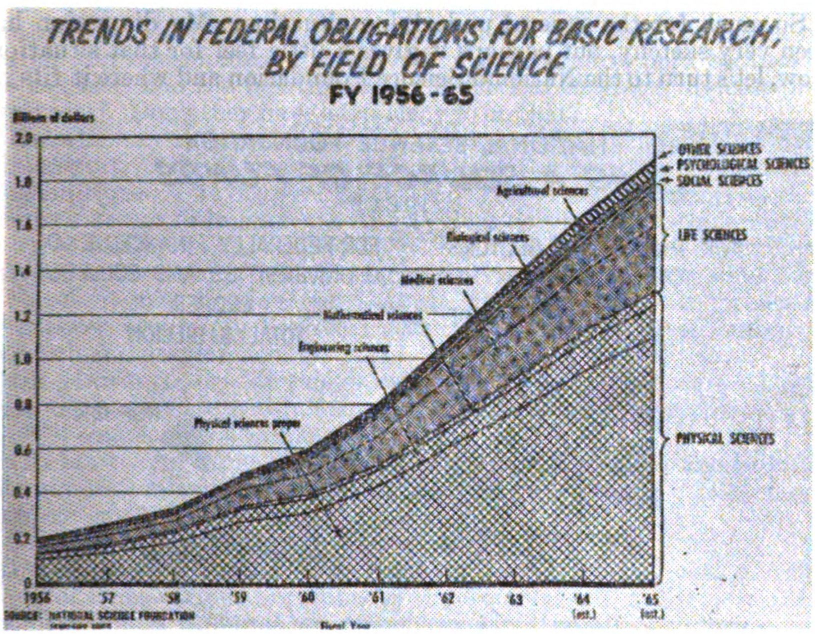

CHART 8

I have included chart 8 for two purposes: (1) to show the trend of Federal support of science and (2) to show the trend of support of various fields.

Here I wanted to show the rate of increase in Federal support of basic research, shown simply by the top line. It is quite substantial, as you see. In fact, Federal support of basic research has grown relatively more rapidly in the last 6 or 7 years than Federal support of total R. & D. I do not remember the relative numbers, but there has also been a higher relative rate of increase in basic research for the country as a whole than in total R. & D.

The other point was to give you some idea of how the support for basic research is distributed among the various disciplines. In fiscal year 1965, this distribution was estimated as follows: about $1.3 billion for the physical sciences, $485 million for the life sciences, $35 million for the social sciences, $60 million for the psychological sciences, and a $2 million scattering for other things. Thus, about 65 percent, or a little more, is in what is here broadly spoken of as the physical sciences, including not merely the physical sciences proper but engineering and mathematics. The life sciences, then, would have something like 25 percent. However, I call your attention to the fact that this is only basic research, and NIH classifies substantially more than half of its support as applied research, that is, its support of clinical research and things of that kind. Therefore, if one included not just basic research, but all research, he would find that the physical sciences would get a bit smaller fraction and the life sciences would get a bit larger fraction.

So much for the general underlying situation. My discussion has been very sketchy, but perhaps it gives a little feel for that situation. Now, let's turn to the National Science Foundation and where it fits in.

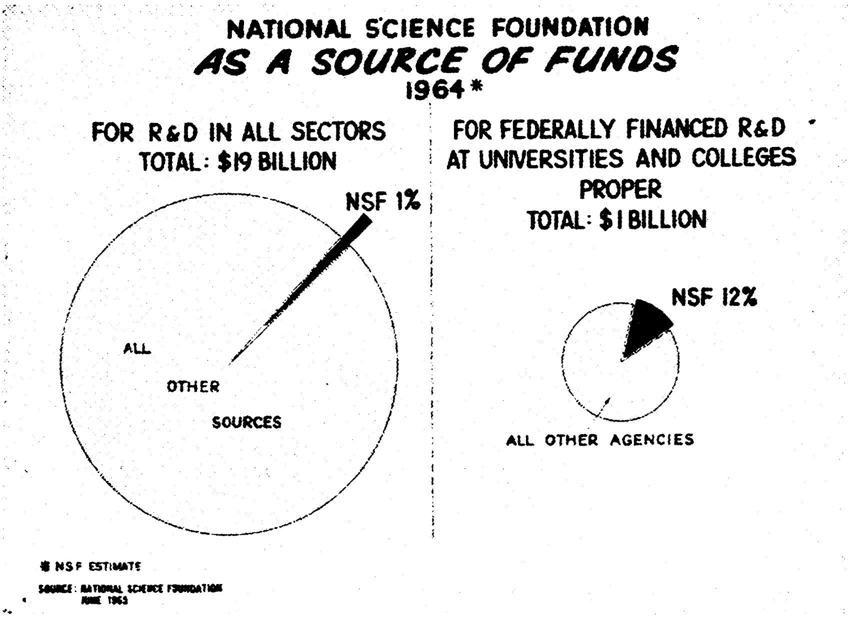

CHART 9

Chart 9, "National Science Foundation As a Source of Funds," is very schematic. It is not even dimensionally correct because if it were you couldn't see some of these things.

The National Science Foundation in 1964, according to our best estimate (circle at left), provided about 1 percent of all the research and development funds spent throughout the country, not just by the Federal Government but by all organizations. Now, if we made this graph actually to scale, the 1 percent would be merely a line, so, in terms of the total R. & D. of the country, NSF financing is pretty miniscule.

Since basic research is about one-tenth of the total R. & D. expenditure, then, if one had a diagram like this for just basic research, NSF would be supporting roughly 10 percent.

Looking at NSF in the total support of research and development at colleges and universities by all Federal agencies (circle at right), NSF supported in fiscal year 1964 an estimated 12 percent. This was about $120 million of R. & D. support in the colleges and universities. Of course, we also supported a somewhat smaller fraction of the basic research supported everywhere by the Federal Government because we don't have in-house laboratories and we don't give any appreciable support to industry. So, of the total Federal basic research it would be something like 10 percent rather than 12 percent. These are some background statistics relating us to the totality.

Mr. Conable. How much confidence do you have in the R. & D. figures for industry? Isn't there a tendency for them to charge research and development to production, for instance, both because of the tax laws and the fact that many industrial contracts are cost-plus contracts? Don't they have a tendency to do that?

Dr. Haworth. I am certainly not aware of any particular slant of that sort. I think there are difficulties with respect to the fuzziness of definitions. I have already spoken of basic research versus applied research versus development. Where does development stop and production design begin, and so on? The definitions even vary from company to company. But I am certainly not aware of any slant here.

Mr. Conable. Do you feel that the statistics you have presented here show accurately the total amount of industry contribution to research and development?

Dr. Haworth. It depends on what one means by accurate. I consider them accurate within a spread of several percentage points.

Mr. Conable. You think so?

Dr. Haworth. None of these numbers should be taken too literally except the numbers that represent how many checks the U.S. Government did write for something.

Those we can be pretty sure of.

Dr. Haworth. Let's look at chart 10 on the "Mechanisms of Support" of these various programs by the Foundation. I discussed these programs in the prepared statement, as you will recall.

Many of our programs—by no means all—clearly serve more than one function. The support of research in a university where there are graduate students clearly serves the purposes of education in several senses. The graduate students participate in research. Some of them may be supporting themselves financially or may be on fellowships and participate in order to get their doctoral thesis. Others are hired as

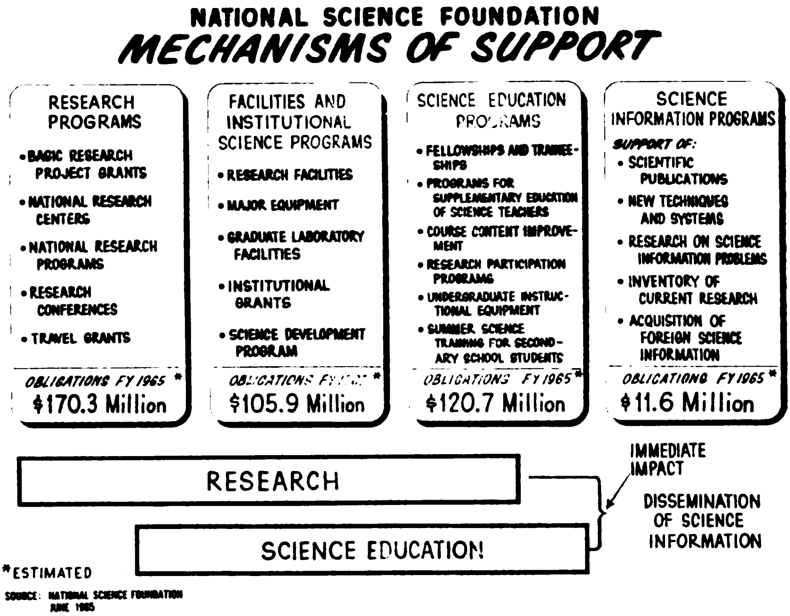

CHART 10

student assistants and participate in research. Of course, this does just about as much good as direct support for the ones who are working on their own thesis.

The fact that the faculty and those graduate students who engage in teaching are lively in their subjects, that they are up to date, and are thinking actively, and so forth, clearly has a big impact on how effective they are as teachers even of undergraduates.

So, as I said, except in some isolated instances, research funds given to universities and to some of the national laboratories—because they have visiting faculty and graduate students—have an impact on education.

Similarly, some of the science education programs have an impact on research—the fellowship programs, for example, because a substantial fraction of the fellowship holders are graduate students at the advanced stage where they are engaging in research for their doctoral thesis. We have tried to indicate by the placement of the rectangles representing the two large functions of the Foundation itself, research and education, that various activities overlie both.

I have indicated or have tried to indicate that most of the research support that we give has an impact on education. Many of the education programs have an impact on research. Then, lying in the middle and affecting both, though one cannot sort them out, are the various institutional programs, such as research facilities, major research equipment, graduate laboratory facilities, institutional grants which the universities and colleges use for these purposes, and the science development programs. All of those programs have an impact on both research and science education, although not in every individual instance.

Finally, at the right is shown the science information programs. They also clearly have an impact on research and education, but in a more indirect way.

You can see here how our funds are divided for fiscal year 1965: \$170 million for out and out research programs, \$120 million for out and out educational programs, \$106 million for the institutional programs, and not quite \$12 million for the science information activities.

Mr. DADDARIO. I have a question, and we will probably run into this again later on, about your science education program for supplementary education of science teachers. In the event that a university had a science major that it might be able to convince to go into the educational field but who was not in fact a science teacher at the time, do you have the capability of providing funds for him under this program, or is there a hiatus there?

Dr. HAWORTH. I think I will let Dr. Riecken discuss that question. This is Dr. Henry Riecken, Associate Director for Education.

Dr. RIECKEN. Could a science major obtain support in studying science to become a teacher?

Mr. DADDARIO. Yes.

Dr. RIECKEN. As a graduate student, he would become eligible for——

Mr. DADDARIO. He would be eligible for the competitive fellowship programs, but my question is directed at this particular program. The question is should the program be enlarged?

Dr. HAWORTH. Let me try. I think I understand now.

This program, supplementary education of science teachers, is directed at teachers already in service. We have not been very active in the sort of thing you have been talking about—the preservice training of teachers—that is a field which we feel we must press forward on. We are doing a little experimenting there already.

The reason for our approach was this: There were thousands of science teachers already in service, already trained, many of them not well trained initially and many of them out of date because they had been out of college so long. As I understand it—this is, of course, well before my time in the Foundation—the reasoning was that the quickest return per dollar could be obtained by putting emphasis on upgrading this very large number that were already teaching. Although it would be nice to do everything at once, with limited resources, choices have to be made. But preservice training is one of the things that Dr. Riecken talks most about being anxious to do. There are experimental programs, but they are not very sizable.

Mr. DADDARIO. At any rate, you are giving thought to putting more money in this area, now that you have had some experience with these programs?

Dr. HAWORTH. Yes. One of the things on which I will say more later is that I believe that throughout our science education programs—except perhaps the fellowships and traineeships—that the Foundation should strive to find new methods, to make innovations, to lead the way. We would hope that not only will our programs have direct impact—as, for example, this supplementary training has had—but also that they will stimulate action by the local and State authorities.

We feel, too, that some of our experimental approaches will be helpful to the Office of Education in the sorts of things that it does, not only for science but for other fields. In other words, in one sense, we want to continue to do research and development on science education, to carry out experiments and find innovations. You have put your finger on one of the things that we feel is very important.

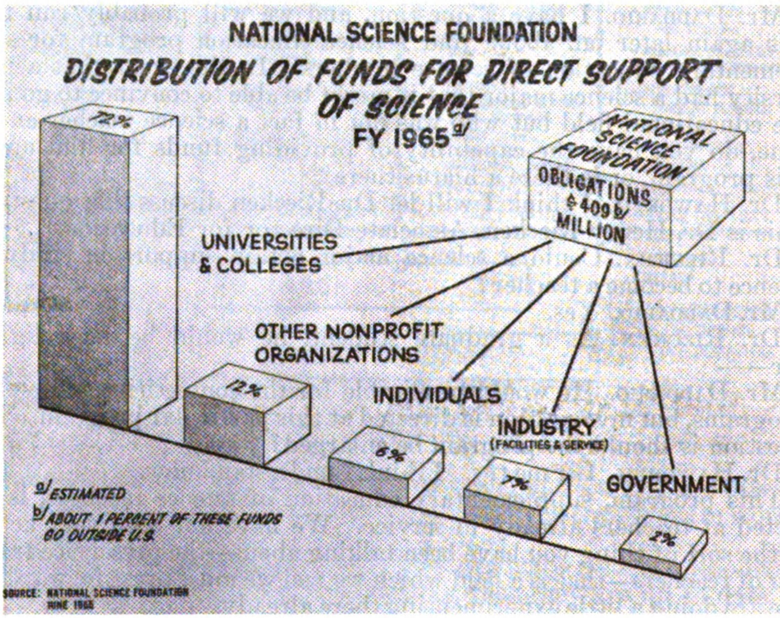

Chart 11

The next thing I would like to show is where our support money goes. These are the same funds that were included in chart 10; chart 11 shows where they go. Again, some of the categories are not sharply defined, as I will explain in a moment. I should say here that the percentages are those of 1964, but the dollar amount is that of 1965. We don't yet have the final breakdown on 1965, of course, but assume that 1965 will show about the same pattern.

Of $409 million of obligations in fiscal year 1965 for the actual support of research and education and information activities—and I am leaving out our own internal administrative cost, the policy planning studies, and things of that sort—72 percent goes to the colleges and universities, 12 percent to other nonprofit organizations, and 6 percent to individuals, meaning primarily for fellowships.

There are a very few cases of research grants to individuals, but they are trivial in number. Seven percent goes to industry, mainly for facilities and services, the largest item of that being for the design and construction of the Mohole equipment. We do not in general support research in industry, but occasionally we must buy things or have them made. Two percent is transferred to other agencies of the Government.

Mr. MILLER. Where does that 2 percent go?

Dr. HAWORTH. For example, in our antarctic program some funds go to the Weather Bureau and to the Office of Naval Research, to help carry out that program, which we totally fund. Another example is Dr. Herbert Friedman's rocket flights. You are fully aware of that program. We provide funds there to purchase rockets, and so forth, for university people who come in and work with Dr. Friedman. Although the work is for the benefit of the university scientists, the arrangement shows up as an intergovernmental transfer.

The bar indicating 6 percent to individuals is one I would like to say a bit more about; the sums involved represent our awards to individuals instead of to organizations. Thus all the Foundation's fellowship programs are included, and indeed constitute the bulk of the funds reported in this bar. The amount includes the educational allowances as well as the stipends to the fellows.

However, this bar does not include our support of graduate student awards under the traineeship heading, since we make grants in this program to universities, and they select the individuals who become trainees. The point I am emphasizing here is that the 6 percent shown for awards to "individuals" somewhat understates the overall situation; we actually devote a considerably larger sum to support of students at various levels. This situation is much the same as the problem of reporting on "prime contracts" versus "subcontracts." You let a big contract to a prime contractor to do some big job, and he immediately subcontracts a lot of it. It is exactly the same situation. So, my main point is that a substantial part of this goes to individuals in this kind of sense. I am not using the payroll sense, but the fellowship and traineeship sense.

Mr. MILLER. Doctor, you have a footnote here, "About 1 percent of these funds go outside the United States." I assume that is the total.

Dr. HAWORTH. Yes.

Mr. MILLER. Are we spending enough in this area?

Dr. HAWORTH. That is a good question. Incidentally, part of that 1 percent is actually going to support Americans. Some of it is going for the translations that I spoke of. There is some support for research activities by foreign institutions. For example, some support goes to the Naples Zoological Station, but mostly because Americans go there and work. However, we are not requiring that it be used to support Americans.

Mr. MILLER. There are European science facilities. I have always felt in the interest of science that we should take advantage of their work. I just wonder whether we have spent enough money in this field.

Dr. HAWORTH. Well, of course, there is a great deal of give and take with Western Europe. For example, one of the most interesting sides of my experience at Brookhaven was the interplay between the CERN Laboratory at Geneva and ourselves. We didn't finance each other in any sense, but we worked very closely together, and were the best of friends.

Mr. MILLER. But there are other areas.

Dr. HAWORTH. I think we should go all out in cooperating in this sense. To what extent we should finance research abroad depends on the circumstances, of course.

One thing is not indicated which is pertinent to this. The NSF does a considerable amount in the way of international science activities. For example, we have a participating agency service agreement with the AID whereby through a transfer of funds to the Foundation we are managing two science education improvement programs in Central and South America. Therefore, we are involved in international programs perhaps somewhat more than the line indicating appropriated funds would lead one to believe.

Mr. MILLER. I had the privilege of attending the dedication of the Air Force astronomical instrument at Arecibo, P.R. The American press were not present but the South American press, El Mundo, had about 10 people there. I have often wondered if this wouldn't be helpful in not only raising the standard of science in these countries, but also in establishing a closer working relationship.

Dr. HAWORTH. I personally feel that cooperation in science offers one of the few windows that show any real promise of solving some of our really important problems of the world. I have had a great deal of personal experience, for example, with Russian scientists. There are some Russian scientists who are very good friends of mine. The antarctic program is another good example. If we can gain a little bit of understanding here or there that can gradually grow, we can help greatly to change attitudes, I think. And that is fundamentally what has to happen.

Mr. MILLER. Last fall a group of this committee went to the Pacific to visit our tracking stations and other facilities, and we spent better than half a day in Manila with General Romulo in the University of the Philippines. As you know, he is trying to develop an Asian center there. He stated that the Asian people will accept that even quicker than anything else because of the relationship that we already have in this area. I thought this was a fine way to perhaps penetrate into this area that is so important to us but giving us so much trouble now, by supporting the work that they are doing, by bringing American educators there, and perhaps by bringing Philippine educators here. It is just like the American University in Beirut. It had a great influence in the Middle East. We ought to be looking for this sort of thing in the Far East. Of course, this is a lot further down the line than we are discussing now.

Dr. HAWORTH. There is a lot of things going on now. I think one of the rather promising activities is the sister relationship that has been established between certain American universities and foreign universities.

Mr. DADDARIO. Dr. Haworth, we will stop here for the day. This committee will adjourn until 10 o'clock tomorrow morning.

Mr. MILLER. Before we go, Mr. Chairman, I would like to express my appreciation to Dr. Haworth and his staff for the very fine presentation they have made.

(Whereupon, at 12:02 p. m., the meeting was adjourned to reconvene at 10 a. m., Thursday, June 24, 1965.)

NATIONAL SCIENCE FOUNDATION

THURSDAY, JUNE 24, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., the Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. The meeting will come to order.

Good morning, Dr. Haworth. Would you proceed, please.

FURTHER STATEMENT OF DR. LELAND J. HAWORTH, DIRECTOR, NATIONAL SCIENCE FOUNDATION

Dr. Haworth. You will recall that when we stopped yesterday I had been discussing chart 11 (see p. 30). A point that I had not quite come to yet was that, in terms of support of individuals for other than services rendered, an important component that could go in the "individuals" box are the institutes where teachers are given individual stipends while participating in further training. Since they receive the stipends through the university or college conducting the institute, the funds actually show up in the universities and colleges box.

In other words, the direct or indirect support of individuals is really two or three times as great as the chart would indicate. I think with that I can go on to the next chart.

I might call attention to the fact that in your books chart 12 is followed by chart 12–A which breaks down the NSF research and education totals in detail. This is to give you a rough idea of how our funds are spent and how they relate to research and education in terms of the way we define these activities. Most of our research funds also bear on education, and many of our education funds bear on research, but this is the way we actually categorize them, according to primary purpose.

In chart 12, we show operational funds, that is, funds supporting actual activities, as distinguished from facilities funds for the purchase or construction of major equipment, buildings, and things of that sort. You will see that in terms of programs which one can classify cleanly, about three-quarters goes to operational funds and about 16 percent goes for facilities. The institutional grants and the science development funds are used for mixed purposes, and we simply do not have any way of subdividing them; that is, we do not have

CHART 12–A

statistics to show how much of the institutional base grant is actually used by a university to renovate a laboratory as distinguished from some operational function.

I would be glad to answer any questions, but I think an inspection of the chart gives a fair idea of the situation.

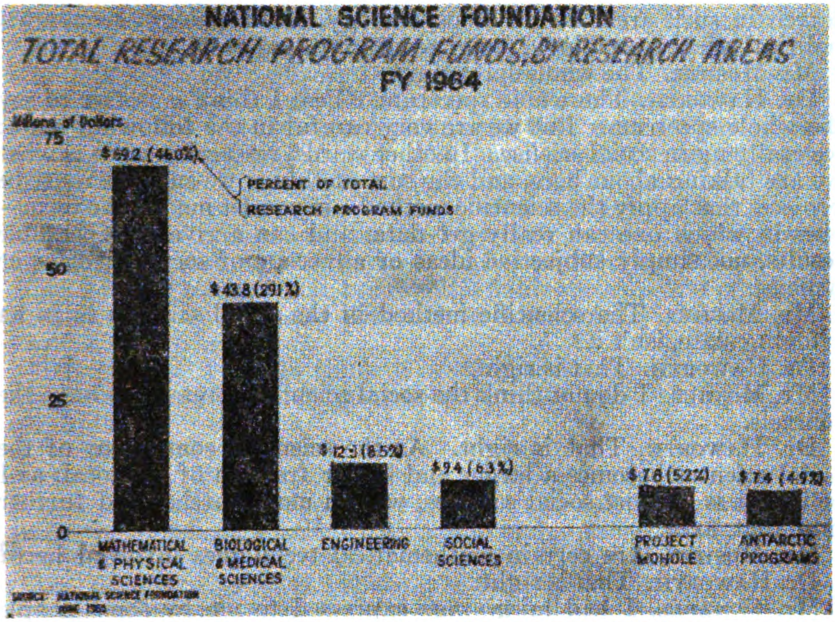

CHART 13

I turn now to chart 13. This shows the relative way in which we support various kinds of research activities in different fields. The first four blocks show the amounts of money granted in support of the various fields in fiscal year 1964, regardless of whether the funds came under the budget heading of research project grants or, say, under national programs, such as the International Indian Ocean Expedition, except for two special cases. We have pulled out Project Mohole and the Antarctic programs separately. The other national programs are included in the first four boxes.

You can see that most of the funds go to the mathematical and physical sciences, which, of course, include the earth sciences, the atmospheric sciences, astronomy, and so on. Again, unless you have questions I won't attempt to go into detail.

Relatively speaking I believe it is fair to say that the proportion of our total research support going to the social sciences has shown the most growth, with engineering close behind. As you know, we didn't start supporting social sciences as early as we did the others, and more attention has been given to the engineering sciences in recent times. For example, only about a year or a year and a half ago we separated engineering science organizationally from the physical sciences, and now it is a full-fledged division of the same stature as the mathematical and physical or the biological and medical sciences.

Mr. MOSHER. Could you give us an indication of where the emphasis lies in the social sciences? Is it psychology?

Dr. HAWORTH. Social psychology was the first one to be supported. Actually, there was not a sudden branching out to cover all the social sciences. Rather they have been included gradually. We support re-

search in such areas as social psychology, anthropology, economics, political science, sociology, social geography, and so on.

Mr. MOSHER. The whole spectrum?

Dr. HAWORTH. The whole spectrum. Yes; I think it is fair to say the whole spectrum. But we are very careful in the following sense: we really mean social science. In other words, research science is what we are talking about here, and the sort of things we support must be projects that apply the scientific method—if you let me use the term—ones in which one can really get data, and can arrive at repeatable results, not simply subjective ideas or advocacy of social theories or policies.

Mr. MOSHER. The scientific method in the social sciences is in an evolving state, isn't it?

Dr. HAWORTH. That is right.

Mr. MOSHER. I do not think the social scientists pretend to have the controls.

Dr. HAWORTH. That is right. As the scientific component of the social sciences becomes a larger and larger fraction of the total, as I believe it is in most social sciences, we can move further and further into that area.

Mr. MOSHER. Are certain mathematical techniques involved here?

Dr. HAWORTH. That is right.

Mr. CONABLE. I had misgivings expressed to me by some people about the establishment of the Humanities Foundation because of the impact it might have on the National Science Foundation's contributions to the social sciences. As you describe it, the two need not overlap at all.

Dr. HAWORTH. I think I would rather say there would be a fuzzy edge. You can say, "something over here we can do, and something over here we cannot do." Just where the break comes in between——

Mr. CONABLE. Even if the Humanities Foundation is established, this is not a reason for you to stop supporting social sciences?

Dr. HAWORTH. That is correct.

Mr. CONABLE. There are some people who feel that the National Science Foundations' contribution to the social sciences is important. They are concerned lest the National Science Foundation discontinue its support of the social sciences if the Humanities Foundation is established because this new foundation can take care of that function.

Dr. HAWORTH. We haven't any intention of doing that. Incidentally, we very much welcome the Humanities Foundation. I think it is badly needed. I think we can complement each other rather than rival each other.

Mr. CONABLE. It would impart a certain symmetry to the program.

Dr. HAWORTH. That is right.

Mr. BROWN. Dr. Haworth, we probably will get into a further exploration of this social science support later, but is there anything in your enabling statute, or is there any administrative restrictions with regard to the support that you give the social sciences or the proportion of your funds that go to the social sciences?

Dr. HAWORTH. Perhaps I can answer your question somewhat obliquely. At the time of the passage of the original National Science Foundation Act, there was lively debate—or discussion at least—as to whether the social sciences should be included, and then the question,

if they were included, how would one define them. This was finally resolved by including in the act a phrase saying that we should support the "mathematical, physical, medical, biological, engineering, and other sciences." It was left then to the Foundation, the executive branch and the Congress, to determine as time went on just what one could define as "other sciences." So, there is no restriction in the sense of any barrier. I guess that answers that part of your question.

So far as the relative support is concerned, this has been, it is fair to say, largely a matter determined by the Foundation itself within its budgetary limitations, and, as I have pointed out, social science came into the picture later because the fields were spelled out and the Foundation was virtually directed to do naturally the things that were picked up first.

Mr. BROWN. I would think it would be natural that those things which are specifically delineated or named would get the primary emphasis.

Dr. HAWORTH. Yes.

Mr. BROWN. With regard to the composition of the National Science Board, I presume that there is a similar emphasis upon representatives from the physical, mathematical, and biological sciences, and relatively small representation from the social sciences?

Dr. HAWORTH. Yes. I believe it is correct that on the Board there is a larger representation of the physical sciences than the social sciences. But the social sciences are well represented, not only because of the fact that we have the research responsibility in these fields but we have responsibility for education, and many of the leading educators come from the social sciences. For example, one board member is Dr. Katherine McBride, the president of Bryn Mawr. She is a psychologist—but she is a member just as much because she is a leading educator as because she is a scientist. That tends perhaps, as I said, to admix the membership a little more than if we supported only research.

Mr. BROWN. In other words, the Board has greater proportion of representation from the social sciences than would be reflected in NSF expenditures for the social sciences?

Dr. HAWORTH. I believe that is true. I haven't thought through all the members at the moment, but I believe that is correct.

Mr. BROWN. Do you have established criteria which you use as a basis for the allocation of your funds between the different branches? I am thinking here in terms of criteria that relate to the importance of the scientific field to the national welfare, or to some other standard that can be either generally or specifically spelled out?

Dr. HAWORTH. The criteria I must confess are rather general and vague. As you know and as I think most of the people who wrote papers for the recent Academy report to this committee said, there is no formula way in which you can decide these things.

One of the important criteria that we have used is simply what is the situation with respect to good research that is being proposed? If, at a given time, we find that we have to turn down relatively more good proposals in chemistry, let's say, than we have to turn down in physics, then we will tend to increase the support in chemistry. It is a little bit like driving a car, or perhaps more clearly like guiding the Explorer to Mars. It has a course, you let it follow it for a while, and

then you find it isn't going to quite the right place, so you put in a correction. The correction is largely based, or has been, on the kind of finding that I indicated. Subjective judgment is involved. It is not a calculable matter, deciding that we are neglecting some field compared with another.

Mr. MOSHER. When you use the words "good proposal," how do you define that? You said there are more good proposals in chemistry than in physics at any one time.

Dr. HAWORTH. No; I said "If we have to turn down a bigger proportion of the good ones." These are evaluated by our own staff and by our panels of advisers. The general picture is looked at by people like Dr. Randal Robertson, the Associate Director for Research and by our divisional committees which cover whole broad areas, not just a single subject. We are in the stage of flying by the seat of our pants, if you want to use that phrase, in this area of balance among fields of science at this time.

Mr. MOSHER. They are evaluated against what criteria?

Dr. HAWORTH. Against the criteria of the proven ability of the man or men proposing the project, against what seems to be, and this is always a little harder to evaluate, the value and potential productivity of the ideas and the proposed course of action. Project proposals are more or less specific on these matters. We certainly don't give funds simply to somebody who says, "I am going to do some research in physics" or "I want to do some research in nuclear physics."

Mr. MOSHER. Productivity of knowledge?

Dr. HAWORTH. Of knowledge.

Mr. CONABLE. It seems to be implicit in what you are saying that any good man with a worthy project is entitled to the support of the Federal Government. Is that a fair statement?

Dr. HAWORTH. I think I would say he is entitled to request support. There isn't enough support to go around to all the good men.

I think I should add one more thing. It is our belief—and this, of course, is subject to question—that the support of science could well be higher than it is. That is, there is good science that would be useful to the country that isn't being done, and so long as that is true, then I would accept what you just said. This is not to say that there won't come a time—there might—when the country will have a high enough level of science and there might be more scientists than we need. I don't foresee that, but it is not inconceivable.

Mr. BROWN. Doctor, I presume from what you have just said here that there is a substantially smaller volume of proposals made in the social sciences than there are in the physical sciences.

Dr. HAWORTH. That is correct.

Mr. BROWN. You are not, for example, funding 50 to 75 percent of the proposals in physics and only 5 or 10 percent in the social sciences?

Dr. HAWORTH. No; we are not. As a matter of fact, at the moment we are probably doing relatively a little better in supporting the proposals in the social sciences. Now, this varies from time to time, of course.

Mr. BROWN. I think we will explore some of these questions a little further, but I just wanted to get some of these points out on the table.

Mr. DAVIS. Would you please make a few comments about the expenditures that are made in the field of engineering? I notice that the field of engineering is 8½ percent of the total. What considerations enter into that sort of outlay?

Dr. HAWORTH. In the first place, we must recognize that the charter of the National Science Foundation does not allow us to cover all the fields of engineering. I don't mean that we cannot have some chemical engineering and some electrical engineering, but we cannot cover all kinds of activities in engineering. We are chartered and directed to pursue basic research. Now, at first sight one would say that would mean we cannot do anything in engineering because in a sense "basic research in engineering" is a contradiction in terms.

One of the things, though, that one must bear in mind is that there is a difference between saying "engineering research" and "research carried out by engineers." Just as there is many a physicist in a chemistry department who considers himself, by now, a chemist although he is doing research in physics, so many an engineer does basic research. Also, we have taken to some extent the view that what you mean by the term "basic research" depends on the circumstance. In the field of high energy physics there isn't any such thing as applied research at the moment. Maybe there will be in the future. So it is all basic research. But to some extent one can take the view—he has to be careful—that research that is basic to some scientific or technical area can be thought of as basic research. That is the view we have taken here. Research that is basic to general principles, to general advances in engineering, is what we define as basic research in engineering.

Mr. DAVIS. Let me think of a project. Suppose somebody were to train a computer how to design something; would you call that engineering?

Dr. HAWORTH. You mean the act of training it or developing it?

Mr. DAVIS. Developing it; yes.

Dr. HAWORTH. I will have to ask Dr. John Ide, Director of the Foundation's Division of Engineering.

Dr. IDE. I would say definitely yes.

Mr. BROWN. Let me give another example in the high energy physics field. Suppose you are concerned with new developments in a high energy accelerator; I am talking about the machine in which you produce the phenomenon which you wish to investigate. Is that engineering or is that physics?

Dr. HAWORTH. In terms of our ability to support it, we consider it definitely a part of the appropriate activities in basic research because it was designed and built to accomplish basic research. The act of building it, designing and building it, is actually a combination of physics and engineering.

Some very basic physics, for example, had to be done to be able to understand the motion of the beams, the particle beams, in the present so-called alternating gradient synchrotrons. For example, physicists combined with the engineers to build the big machine at Brookhaven. It is a tool for basic research and its cost is, therefore, a legitimate expense to be charged against basic research.

Mr. BROWN. Is it basic engineering research or basic physics research?

Dr. HAWORTH. In this case we would charge it to basic physics because the objective was basic physics.

For example, we are supporting the design and construction of an electron synchrotron at Cornell University; it will cost about $12 million. Actually, this column in chart 13 does not include facilities costs. But if we had a facilities cost in here, we would put that cost in the mathematical and physical sciences, not in engineering, even though a great deal of the activity is engineering.

Mr. DAVIS. I would imagine it is often hard to decide in what column to put an expenditure.

Dr. HAWORTH. It certainly is. Sometimes they belong in two or three columns. Much of this assignment is arbitrary.

Mr. MOSHER. Is isn't a very important question, is it?

Dr. HAWORTH. Not in this kind of sense.

Mr. MOSHER. I wouldn't think so. It is strictly for statistical purposes, isn't it?

Dr. HAWORTH. That's right. However, classification is important in terms of trends and things of that sort. The most important thing is to be consistent about classification from year to year.

Mr. MOSHER. As a tool for evaluating your policy?

Dr. HAWORTH. As a management tool, yes.

Mr. DADDARIO. It may be just a management tool from the statistics standpoint; however, you may not get the funds for the program if you put it down in your budget request as basic engineering, as Mr. Brown has pointed out, rather than basic research in physics. How you label it is unimportant after the fact, but it is extremely important as to whether you get the program going in the first instance.

Dr. HAWORTH. In the first place, you must be consistent. In the second place, everybody that uses the data must understand how it is made up, which would be essential to the point you make.

Chart 14 shows how the funds that are given out for basic research grants are distributed. Here we are leaving out the national centers and so on. These are the grants to individuals or small groups of individuals—or rather to the universities and colleges and other institutions to support the research of individuals, or groups of individuals. This chart shows how those funds are expended. Not quite two-thirds goes for salaries and wages. About 15 percent goes for permanent equipment. Major equipment is excluded; these are items which cost up to a few thousand dollars. Nine percent is for expendable equipment, supplies, and so forth; a very small amount is for travel and scattered other expenses.

Then, at the right in order not to clutter up the circle at the left too badly, we show the salary component separately. Salaries reimbursed for the principal investigators is about 13 percent of total direct costs. About half or perhaps a little more salaries for them is for summer work. In general, their academic appointments do not carry through the summer and they are given research appointments that we reimburse. The rest is the reimbursement for that part of the time that they spend on our research in the regular academic year. We are not covering all of that cost; that is, we are not reimbursing all of that cost.

Faculty associates account for 4 percent of the total; they are members of the faculty other than the principal investigator.

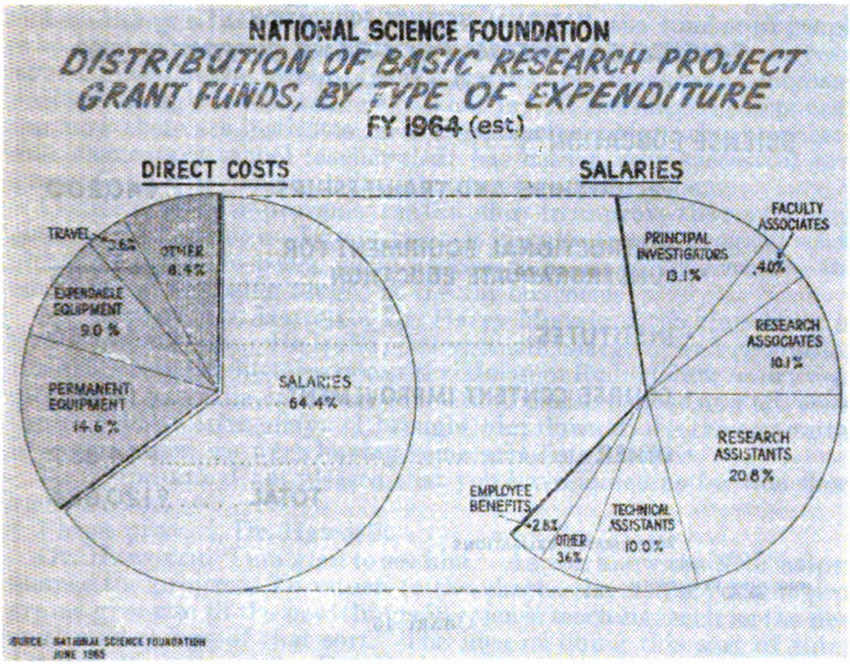

CHART 14

Ten percent is for salaries of research associates. These people work for 2 or 3 years after receiving their Ph. D.'s as an extension of their graduate education.

Twenty percent is for research assistants. Those are predominantly graduate students who help earn their way by employment as assistants on research projects, just as many graduate students help earn their way by part-time teaching.

Then, there are the technical assistants, 10 percent, other kinds of people, and employee benefits.

So you can see, as I said, that about two-thirds of direct costs goes for payroll in one form or another.

Let me now turn to chart 15, the Foundation's science education programs. I have been talking up to now about the types of research support. I will now talk about, science education—fellowships and traineeships, teacher training, course content improvement, research participation by teachers and undergraduates, and so on. Here is the breakdown for fiscal year 1965 of our allocations of funds that are specifically identified as science education, which total \$120 million. About a third goes for fellowships and traineeships; the preponderance of these go to graduate students.

This category also includes faculty fellowships, postdoctoral fellowships, and so on, but they comprise a small fraction of the total. The next category represents grants to colleges and universities, primarily to colleges, to buy instructional equipment for undergraduate instruction. It may be equipment for lectures or teaching laboratories or both. These grants run from a few thousand to several thousand

CHART 15

dollars—$10,000, $15,000. They are given, incidentally, on a 50–50 matching basis. The institution must provide the same amount that we do. These go, I believe, to between 500 and 600 colleges and universities each year. There are more grants than that, but in some instances there is more than one grant to a given institution.

The institutes I spoke of yesterday are of three kinds, as I said: First, there are the institutes conducted for teachers during their summer recess. They are of the order of 6 to 8 weeks long. The teachers try to get caught up on the material in the particular fields they teach. The institutes are conducted by colleges and universities that make proposals to us. The best are selected. Again we can fund only a fraction of the proposals.

The institution selects teachers—the institute trainees, if you want to call them that—from among persons who apply to the institute for admission. The institute is conducted in accordance with the college's plans. We fund the institute, and the institute pays nominal stipends to the teachers who have given up summer employment to go to these institutes.

Second, during the academic year there are so-called inservice institutes in which the teachers take similar training at night, on Saturdays, and other offduty hours, as an extracurricula activity. They are not given stipends because it is during a period when they are earning anyway.

Finally, there is a relatively small number of so-called academic year institutes, in which the teachers take a leave of absence from teaching duties for a school year to attend the institute and again, they are given a stipend because they are giving up earnings during this period.

I will show a little later, I believe, statistics on the number of people who have participated in these institutes. They started a dozen years ago, I guess, at the level of college teachers but quickly the emphasis shifted to high school teachers. That is still the largest component, but now there are institutes for college teachers, high school teachers, and elementary school teachers. It has been a very successful program, but I will come to relevant statistics in a moment.

Course content improvement is the effort to improve the content and general methodology—I don't mean it in quite the pedagogical sense, although there are pedagogical aspects to it—of the curriculum and courses that are being taught at the various levels.

Mr. MILLER. Dr. Haworth, Dr. Harry Messel, of the University of Sydney, is with me. He is the man who is in charge of and is building the Mills Cross radio telescope at the Molango Radio Observatory near Canberra, Australia, in connection with Cornell, to make new advances in the field of astronomy. I brought him down to see the committee in action when we were having some scientists testify.

Mr. DADDARIO. I am pleased that you have joined us for this short visit, Doctor.

Please proceed, Dr. Haworth.

Dr. HAWORTH. I am glad to see him. As you know the NSF helped finance the project. To return to the charts, the course content programs give rise to the new things in science teaching, such as the new math and things of that sort. The idea of doing this sort of thing did not originate in the Foundation; people like Max Beberman, at the University of Illinois, were already doing this before we got started in it. Nevertheless, it has been heavily supported and gives great momentum by the Foundation.

In particular, a technique that has been very successful in this—and one, I think, largely responsible for the great success—was developed in some of the projects supported by the Foundation. This technique, which several groups have used—one of the well known ones being PSSC, the physical sciences study committee that started originally at MIT under Dr. Zacharias—is to get together a group composed of leading research scientists plus science teachers at every level, plus school administrators, and meld together the different kinds of knowledge and information and ideas and experience that these groups of individuals have in order to produce a sensible, up-to-date, interesting, and inspiring course or curriculum. This is far more successful than to use either a physicist who is far away from high school kids and doesn't really know anything about handling them or what they can absorb, or a high school teacher who doesn't really know the up-to-date science. It is just like the situation in which both physicists and engineers are needed to build an accelerator. It takes several kinds of people to devise a curriculum. It isn't merely textbook writing. It is textbooks, plus laboratory equipment, plus increasing introduction of movie clips, plus background material for the teachers themselves that doesn't go to the students but helps the teacher to be a better teacher—the whole complex of things. This activity has been very successful. It is being actively carried out in physics, in biology, in chemistry, in math, and increasingly now in the earth sciences, and branching out into the social sciences, and so on. Again, it started at

the high school level. It has moved in both directions, into the college level and into the elementary school level.

One of the things that helped push along its introduction at the college level is that the youngsters who are coming out of the courses in high school that use these new materials and who study under retrained teachers just know too much for the old college textbooks. So, it has had a pushup effect.

Mr. DADDARIO. Do any of the other agencies, such as the Office of Education, also have programs in this field?

Dr. HAWORTH. Yes. As a matter of fact, we support a program or two jointly. They are tending to emphasize more the areas where we do not reach, but they are increasingly using this technique, and I think eventually, under various kinds of auspices, the Office of Education, the States, and so on, it will cover the whole area and the whole country.

Mr. DADDARIO. Are these programs being proposed with full knowledge of what the other agencies are doing? You do coordinate with the Office of Education, do you not? Do they know what the Foundation does, and do you know what they are doing?

Dr. HAWORTH. Yes; there is very close cooperation. It is especially close in this area.

Mr. DADDARIO. It is a program that is developing on a proper cooperative, rather than a competitive and duplicating basis?

Dr. HAWORTH. That's right. One thing I will be very careful to say is that we do nothing to promote the use of these materials whose development we have supported. That is, we put no pressures, no Madison Avenue salesmanship in the use of these. Rather we develop them, that is, the people whom we support develop them—I have to be careful about that, too—they become available, and, of course, it is up to the local authorities as to whether or not they use them.

Mr. DADDARIO. You mean you don't push at all in setting up a pilot program?

Dr. HAWORTH. We do in that sense, but that is part of the development process. What happens is an evolutionary process. One of these groups will get together and plan what they think is a reasonable course of action. A very common technique is to have a so-called summer writing session in which a substantial number of people get together and prepare materials. These are then published, not in hard cover books but in mimeographed form, and tried out in a number of schools, which use them voluntarily, of course. Then, as the result of that trial, usually of a year's duration, the materials are reworked and improved. Frequently materials go through more than one such phase, ultimately they are turned over by contract to a regular commercial publishing house which publishes for the open market.

The purpose of the remark that I wanted to be very careful to make was that we are not trying to influence the decision of the local and State school authorities with respect to the adoption of the materials.

Mr. DADDARIO. You make it available, and if it is good enough you expect——

Dr. HAWORTH. We expect it to sell itself. Incidentally, we are also careful, not to make any distinction in teachers institutes as to

whether or not they base their instruction on these materials. Some of them do, some of them don't. For example, in the summer teachers institutes. We are not biased. If the people are good and the planning is good but they don't propose to use the updated material, the last does not hurt their chances of getting a grant.

Mr. BROWN. We continue to increase the funds for science education through the NSF, and there has obviously been a dramatic increase following the sputnik in 1957. At the same time we continue a rapid increase in the funding of support for education through the Office of Education, and this has become quite rapid also in the past 3 or 4 years. As a result, it seems to me that we are going to have a continuing problem with regard to delineating the respective areas and determining functions which are appropriate. Is there some type of analysis being made toward the resolution of this problem?

Dr. HAWORTH. In the first place, let me say readily that it will require great care to do this. In the second place, let me say that there is quite close knowledge and cooperation between the two agencies. For example, Mr. Keppel head of the Office of Education, is a member of our advisory committee on science education. Dr. Riecken, our Associate Director for Education, is a member of some of the office and education advisory committees. And there are other cross links of this sort. In the third place, all up and down the staff level there is constant communication. We are doing this in an informed way.

Then, fourthly, let me say briefly what we believe our role in science education should be primarily. First the graduate level of science education, I think, is clearly one that predominantly should be the Science Foundation's responsibility. One of the important things that leads me to say all the things I am going to say is that the National Science Foundation is the agency of the Government that has the most intimate contact with the scientists themselves, especially in the universities: it knows where the good scientists are; it knows where good scientific work is being done. Now, at the other levels, and especially at the high school and elementary school levels, I believe that our role in science education should be one of leadership and innovation. Again, it is helpful that we know what places have good science departments that can really, for example, conduct a good institute, or what organizations are strong, or what people they propose to get together to make a curriculum study and so forth. The thing we should not do is to get into a massive across-the-board support of education, even science education, school district by school district. That is clearly at the other end. Then there is a whole range of things in between, and inevitably we may have some overlap. But I believe that sensible management in both agencies can make this combination a strength rather than a weakness, two agencies with somewhat different points of views.

Mr. BROWN. I feel this is true, but by the same token it may be true that sensible guidelines by Congress may be helpful in eliminating unnecessary proliferation.

Dr. HAWORTH. That may help also. Of course, the Federal programs in support of education through the Office of Education are growing so fast and are changing so fast that it is presently a little hard for me to really sort out and really see the full picture. Incidentally, when I say they are growing so fast, I am very strong for it.

Mr. CONABLE. Does the National Science Foundation have any interest or control over the end product of the course content improvement? You said you made it available after it has been thrashed out. Is this done between the researchers themselves and a regular commercial publishing house?

Dr. HAWORTH. That is right.

Mr. DADDARIO. The House is meeting today at 11 o'clock, Dr. Haworth, but I think we ought to continue until the first quorum call.

Dr. HAWORTH. A contract is made between the publisher and whatever organization carried out the curriculum development. It must be approved by the Foundation. The publisher pays a royalty to the grantee, and those royalty funds come back to the Treasury.

Mr. CONABLE. The money comes back to the Treasury?

Dr. HAWORTH. Yes.

Mr. CONABLE. So, you are reimbursed——

Dr. HAWORTH. Fractionally. Not the Science Foundation, but the Government. The royalties go into the general funds of the Treasury. What fraction of the original development cost will be repaid in that way over the long pull is hard to predict. It is now, of course, only a small fraction.

Included in the last line of chart 15 are a number of other programs. For example, the program for helping undergraduate students to participate in research at their own college or university is included. The funds are partly for the equipment and the supplies they use up. In some instances funds go for stipends for the promising student in financial need, or in the summer, when a student might be giving up employment by doing research. This gives good students a chance to do research and see what a science career is all about, as well as to learn. I think it is a very good thing.

Mr. MOSHER. Mr. Chairman, at some point are we going to get into a discussion of how the institutions are paid for overhead costs? What formula or limits are used?

Mr. DADDARIO. I had not expected that we would, Mr. Mosher, because we covered that subject in our hearings a year ago.

Mr. MOSHER. I think a progress report would be interesting at some point in these hearings because it still is a matter of controversy among the institutions.

Dr. HAWORTH. I am not very well informed as to what their attitudes have been since the action on the bill for health, education, and welfare, which covered NIH, and the independent offices bill, which covered us, which followed your advice.

Mr. MOSHER. When did that come up?

Dr. HAWORTH. At least our bill has only passed the House.

Mr. MOSHER. It isn't effective yet.

Mr. DADDARIO. I feel that we should wait and see how the revised Circular A-21 works out. We are kind of at the fulcrum point on this.

It appears that the Senate will go along on this, and we will have an opportunity to judge it throughout all the Government agencies. The circular does not affect just the National Science Foundation, but all agencies dealing with research. We ought to know in the next year how it works.

Mr. MOSHER. I agree.

Dr. HAWORTH. I will just mention one or two more things here.

Mr. DADDARIO. Could you finish up in a few minutes, Dr. Haworth, because the bells have just rang for the first call.

Dr. HAWORTH. Here in the last item on chart 15, are some experiments in setting up relationships between colleges and high schools to improve the high school teaching situation, and between colleges and universities to improve the teaching situation in the colleges. For example, in the State of Nebraska the university brings in teachers from the colleges and they spend a year at the university at the expense of the college. We help by reimbursing the college for that because they have to hire someone else to fill in for that year. The people go back to their colleges a lot more knowledgeable and better college teachers than they were when they left. Also, we are supporting a few projects for the preservice training of teachers.

NATIONAL SCIENCE FOUNDATION

FUNDS DIRECTED PRIMARILY TOWARD SUPPORT OF SCIENCE EDUCATION

FY 1952-64

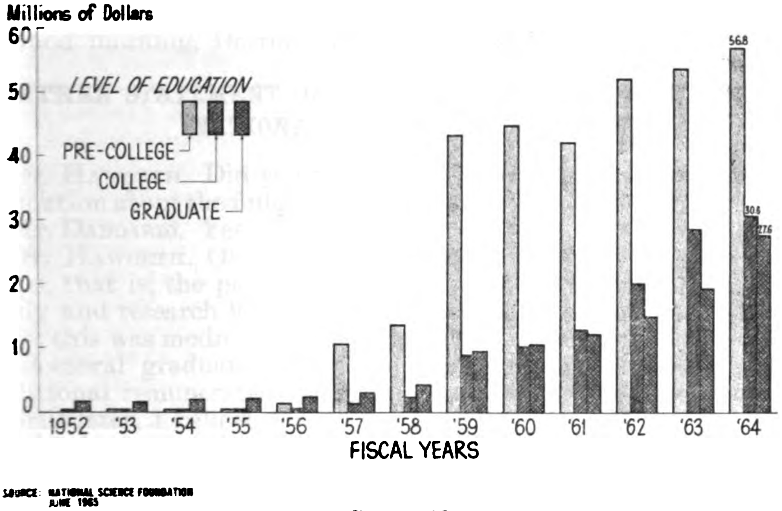

CHART 16

I think that on chart 16 this is fairly self-evident. You can see that, as was said, there has been a considerable growth since sputnik, although it took place fairly rapidly and has somewhat leveled off since with respect to the precollege sorts of things. On the other hand, at the college level there has been a little more of an increase in the last 3 or 4 years. This is partly because we have moved on in these two programs (indicating chart 15) from the high school to the college level.

At the graduate level this step-up between 1963 and 1964 indicates the result of the study for the President's Science Advisory Committee, by a panel of that committee chaired by Dr. Gilliland; it recommended very strongly that there be more support for graduate students in the physical sciences and engineering with emphasis on engineering. We put in our traineeship program in 1964; it is largely responsible for the step-up between 1963 and 1964 in the bar for the graduate level.

Mr. DADDARIO. Dr. Haworth, I would like to finish with a question which we could take up tomorrow morning. The emphasis which you have laid to the improvement of teaching and to the importance of this calls to my mind the problem in the academic community, concerning the limitation on fellowships so far as their teaching loads are concerned. Would you make some comment on that tomorrow morning?

This committee will adjourn until tomorrow morning at 10 o'clock. It has not been my original intention to meet Fridays, but I would like to meet tomorrow so that Dr. Haworth can finish his presentation. I would appreciate it if you can be available, Dr. Haworth.

Dr. HAWORTH. Oh, yes.

Mr. DADDARIO. Fine. Thank you.

(Whereupon, at 11:05 a.m., the meeting was adjourned to reconvene at 10 a.m., Friday, June 25, 1965.)

NATIONAL SCIENCE FOUNDATION

FRIDAY, JUNE 25, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee), presiding.

Mr. DADDARIO. The meeting will come to order.

Good morning, Doctor. Please start where we left off yesterday.

FURTHER STATEMENT OF DR. LELAND J. HAWORTH, DIRECTOR, NATIONAL SCIENCE FOUNDATION

Dr. HAWORTH. Did you wish me to respond to your request for information about the fellowship program?

Mr. DADDARIO. Yes.

Dr. HAWORTH. Originally, the fellowships were full-time fellowships, that is, the people were expected to devote their full time to study and research leading to their degree. Very early, I believe in 1955, this was modified to allow the fellow—I am now talking about a predoctoral graduate fellow—to engage in some teaching without additional remuneration by arrangement with the Foundation.

Still later, I believe for the academic year 1961–62, it was further modified to allow the university to pay from its own funds an additional stipend for a reasonable amount of teaching. At the present time this supplement may be up to a thousand dollars per year. Now, this is done, of course, for two closely related reasons. First, it is clearly worthwhile in the training of students to have them engage in some teaching, and second, and perhaps more importantly, it is, to the benefit of the country that these people get some teaching experience during their formative graduate years. So the two predoctoral fellowship programs—the graduate and the cooperative graduate programs and the traineeship program, have this permissive arrangement.

Now, a small number of the fellows engaged in teaching even before they were allowed to receive additional remuneration. Of course, the number increased when they were permitted to receive some pay for teaching. The last year for which statistics were taken, about 33 percent of the regular graduate fellowship holders did engage in some teaching and the numbers for the cooperative graduate program were comparable. We did not then have the traineeship program, but there is no particular reason to believe it would be any different.

Now, this permissive supplementation of a thousand dollars per year by the institution should be put in perspective. The stipend level for the first year fellow is $2,400 and $500 is allowed for each dependent. If he is in his terminal year it is $2,800 plus dependent allowances. To this, a fellow or trainee may add up to $1,000 by teaching.

Mr. DADDARIO. Do you limit the extra stipend to a thousand dollars because that seems to be the figure——

Dr. HAWORTH. That seems to be a reasonable figure. Obviously, we don't want the fellows to do nothing but teach; they are, after all, fellows in order to go to school. That seems to be a reasonable figure in terms of the amount of teaching that would be appropriate.

Mr. DADDARIO. That would cover the time that he would be able to add to his fellowship?

Dr. HAWORTH. That is essentially the idea.

Mr. DADDARIO. When you say that the figure jumped to 33 percent, Dr. Haworth, what did it jump from?

Dr. HAWORTH. It was around, as I recall, 12 or 13 percent, before any supplementation was permitted, and then when the universities were permitted to pay, it jumped up I believe the first year to 25 percent and then the next year to 33 percent.

Mr. DADDARIO. Is 33 percent a good figure? How do you judge it? Should there be more of these men and women participating?

Dr. HAWORTH. Personally, I would like to see more. The decision is, of course, made by the fellowship holder himself, and the university. In some instances the university and perhaps the professor that he is studying under do not want him to teach. But those are decisions made locally, by the professor, the university, and the fellow.

Mr. DADDARIO. Then part of the stimulation has come from the change to allow the $1,000 addition?

Dr. HAWORTH. Yes, sir.

Mr. DADDARIO. The rest of it, then, would involve university action, wouldn't it?

Dr. HAWORTH. Yes. One thing we should bear in mind, of course, is that this doesn't mean that only 33 percent of the fellows do some teaching at one time or other, because many of them hold fellowships for 2 and 3 and occasionally even 4 years, and this is just how much teaching was done during a given year.

Mr. DADDARIO. Yes, but it would be during that period——

Dr. HAWORTH. I mean that some of the other 67 percent who did not teach in 1962–63 might have taught in 1963–64. So far as the count of individuals is concerned, it is almost inevitable it would be more than that, during sometime in their fellowship.

Mr. DADDARIO. I see that, but these are people who are extremely talented. You would expect they would have a great impact on the students if they did carry a teaching load.

Dr. HAWORTH. Yes. That is right.

Mr. DADDARIO. It might be more helpful at that time rather than a later or earlier time. There might be greater continuity to it. This is obviously something to which you have given attention, and there has been additional teaching carried out. I have asked the question because I have had an opportunity to discuss this with some of the academic people. They are concerned, and do feel, as you have said,

that the universities could apply some more thought to it to see if this percentage figure could be raised.

Dr. HAWORTH. This has been, as you imply, given a great deal of attention over the years by the staff, by the National Science Board, in careful consultation with the university deans and faculties.

Mr. DADDARIO. When you say the $1,000 additional stipend did activate the teaching to this extent, is the limit on the figure an inhibiting factor, too? Should that be raised?

Dr. HAWORTH. I am afraid I couldn't answer that question. Dr. Fontaine, who is in charge of the fellowship program, might wish to comment.

Dr. FONTAINE. Mr. Chairman, we endeavor to keep in touch with schools on this matter through what we call a "coordinating official" at each Ph. D.-granting institution in the United States. Through a series of meetings held in April, for example, it was rather clear that within this $1,000 supplementation framework the institutions felt that they could take care of the majority of the cases where the individuals wished to teach and the institutions wished to supplement the stipend. Perhaps I should point out that we do not require the institution to supplement the fellow's or trainee's stipend.

Mr. DADDARIO. I understand that.

Dr. FONTAINE. But if they do wish to supplement, and I would say—based on the opinions expressed by these people that I referred to as "coordinating officials," usually graduate deans—that they still feel this is an appropriate amount. We have adjusted it from an earlier base—a lower base—to the $1,000. So, it has not always been $1,000. We have tried to keep this in mind.

Mr. DADDARIO. It would be helpful if we could have for the record information on how this was adjusted from one figure to the other over the course of the program. Could we have that data?

Mr. HAWORTH. Yes.

(The information requested is as follows:)

CHANGES IN AMOUNT OF SUPPLEMENTATION FOR TEACHING

Graduate fellowships.—Prior to the academic year 1961–62, a fellow's stipend could not be supplemented by his institution for teaching. In 1961–62, the Foundation, after approval by the National Science Board, allowed the fellowship institution to supplement the fellow's stipend by an amount not to exceed $600 per annum.

The $600 teaching for pay permissibility was continued through the 1963–64 fellowship year. Following a further study of the problem and after conferring with the graduate deans of all institutions granting the Ph. D. degree in the sciences in the United States, the Foundation in the 1964–65 fellowship year increased the permissible supplementation to $1,000 per annum. In 1964–65, the same supplementation amount ($1,000) was permitted in the graduate and cooperative graduate fellowship programs and in the graduate traineeship program, and it is at this same level for all three programs in 1965–66.

Dr. HAWORTH. I should like to emphasize a point that Dr. Fontaine made. We don't require that they give a supplement, nor do we require that it be a thousand dollars; but it cannot exceed $1,000 per year.

Chart 16 (see p. 47) shows the growth of support for science education broken down into a different set of categories, that is, broken down according to whether it primarily affects precollege education, undergraduate, or graduate education. In the first box, of course,

are those things that relate, say, to high school teacher training or supplementary training because the eventual impact that we are after, of course, is at the precollege level. So with respect to the secondary teacher institutes, for example, although the instruction is at the college level, the eventual hoped-for impact is on students at the precollege level.

You can see how these have grown. I believe I talked, as a matter of fact, a bit about this yesterday.

NATIONAL SCIENCE FOUNDATION

SUPPORT OF INDIVIDUALS UNDER SELECTED SCIENCE EDUCATION PROGRAMS

PROGRAMS	CUMULATIVE NUMBER OF STIPENDS PROVIDED [a]	NUMBER OF PARTICIPANTS (FY 65)
GRADUATE FELLOWSHIPS & TRAINEESHIPS	34,300	6,800

JUNE 1965

CHART 17

Next, chart 17, is an attempt to give an impression about how many individuals have been affected by the various education programs, that is, affected directly through their own participation.

Clearly in the training of teachers the real impact that we are after is ultimately on the students of those teachers and we have no way of counting the number of students so affected. If we look first at the last column which shows the annual rate this year of the support of various fellowship holders and teachers and so forth, there are 6,800 predoctoral fellowships and traineeships, 400 postdoctoral fellowships, for 4,700 college teachers in programs of one sort or another including the summer institutes and things of that sort. Also included are science faculty fellowships for college teachers who take a year's leave of absence and go to a university to continue their study. Included also are programs for undergraduate students (including an undergraduate research participation program); programs for secondary school teachers (the bulk of this being the institutes about which we have already spoken); and programs for secondary school students, where we give them a chance to take part in some science activity in the summertime. The latter are primarily projects in which

the students attend courses given in the summer by college and universities, rather than in high schools. Typically, the courses are not advanced high school courses, but are very special studies the students would not otherwise be able to undertake. Finally, included are institutes for elementary school teachers. As you see, all this is relatively new.

In the first column we try to give an indication of the cumulative effect over the years. For example, 34,300 is the number of graduate fellowships and traineeships that have been given. The data do not represent, however, the number of different individuals, because many individuals hold fellowships or traineeships for more than 1 year. We don't have at hand statistics on the number of different individuals. That is, this very impressive number down here, 253,300 grants of stipends to secondary school teachers, does not represent 253,300 different teachers—although clearly the latter is also a large number—because while many of them attend only one institute, some attend two or three. There is a limit on summer institute attendance, however; now teachers may not receive stipends in summer institutes for more than 32 weeks all told. This is not because we wouldn't like to be able to support an individual teacher for more than 32 weeks but, within the limits of available funds we want to spread the support among many teachers needing help.

As you can see, there has been a sizable number of secondary school teachers affected by this program. You can also see that participation has been growing at an increasing rate because the number in the last year is around 15 percent of the cumulative total for something like 13 years. In the next 2 years we will double that.

Mr. DADDARIO. How do you expect the program for the elementary school teachers to develop over the course of time? As you say, it is a relatively new one. What is its prospect for the future?

Dr. HAWORTH. It is growing. I don't recall how much difference there is between this year and last.

Dr. RIECKEN. It has been a gradual increase. I will give you the number for the record.

National Science Foundation institutes for elementary school personnel—Program history

Fiscal year	Proposals received	Amount requested	Stipends requested	Institutes granted	Amount granted	Stipends granted	Actual attendance
1959	90	$2,585,207	3,572	23	$550,900	855	893
1960	127	4,124,640	6,147	28	590,090	950	1,004
1961	196	5,478,926	7,379	54	857,630	1,664	1,812

[1] Estimate.

Dr. HAWORTH. There is, of course, a tremendous number of elementary school teachers, more than a million. Because of their great numbers, we realize that we can't hope to reach them all directly. So we have made a special effort to reach the key teachers—the leaders—in the hope that each such teacher will attend one or more institutes and, after returning home, will inspire and help the others.

Special attention has been paid to that in this program for elementary school teachers.

Mr. MOSHER. And special attention to teachers in science?

Dr. HAWORTH. This is all for teachers of sciences or mathematics or, in the case of college, engineering also.

Mr. CONABLE. Does this represent a very new program, or does it represent a new interest in science in the elementary schools, or does it represent both?

Dr. HAWORTH. It is both. I don't recall when this started.

Dr. RIECKEN. In 1959 we started helping elementary school teachers.

Mr. CONABLE. But it has meant a shifting of the curriculum to include more science instruction in the elementary schools?

Dr. HAWORTH. Yes. The important thing to note is that mathematics is included here and represents the bulk of the program. There is getting to be more, and feeling among educators, of course, especially among scientists who are interested in education, that science education in the lower grades should have an increased importance, not only for its own sake, but also because the study of science is a way to get the student to begin to appreciate the importance of logic and proof—of understanding the rules of evidence in a nonlegal sense. The student of science learns to base his conclusions on facts. Science teaches him a way of thinking logically as well as simply conveying some facts to him.

We believe that something like half of the high school teachers of science and mathematics have now been reached by these programs, but many inadequately.

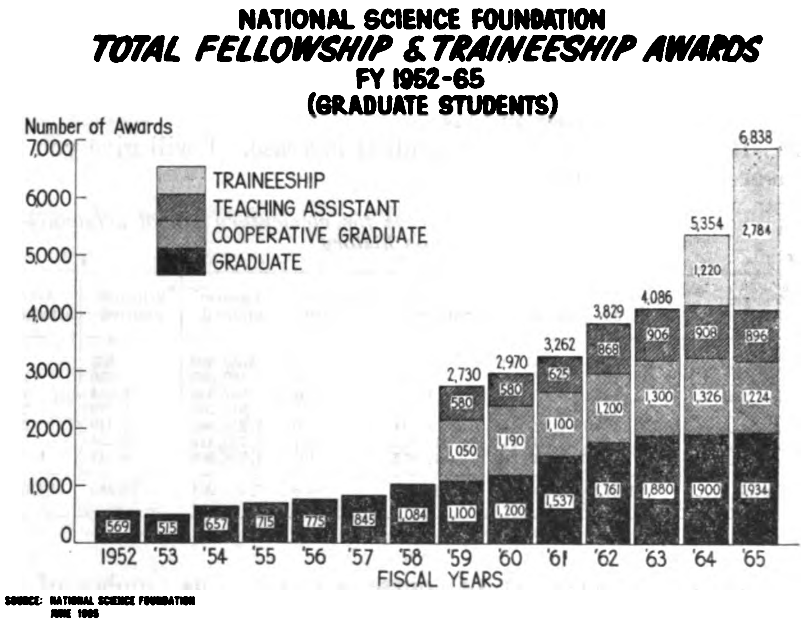

CHART 18

Chart 18 shows the growth of the fellowships, breaking them down a little further now by the various fellowship and traineeship awards for predoctoral graduate students. You can see that new programs have been added from time to time, the original program being what we now call the regular graduate fellowship program. It is the one that is based on a straight national competition in which individuals make applications, compete nationally, and are judged by central panels of scientists, and the best selected.

This is the program I was speaking of the day before yesterday, when we were talking about the geographic distribution of fellowships. Incidentally, I should correct one thing I said at that time. I said that had the 10-percent limitation been in effect this year, we could not have given any fellowships to residents of New York State in quality group 2. Actually, we did not, even without a limitation. Even so, 15 percent of our fellowships were given to people who declared themselves to be residents of New York State. So that with a 10-percent ceiling we would have to eliminate some New York residents in quality group 1 next year.

Mr. DADDARIO. As I understood your comment, you indicated it was not a good thing to have this residence limitation because it would affect your ability to support the highest quality people.

Dr. HAWORTH. Yes. Mr. Chairman, I am in favor of having good universities and colleges in all parts of the country, all regions of the country; I am also in favor of giving opportunity to every individual to develop himself as far as he can. But I think in the national interest we must have some programs, be they for research or for fellowships, that must be administered purely on the quality basis. We must keep them separate; we must not fuzz up the quality programs by other considerations such as geography. Let's achieve such goals with programs that are designed to develop better institutions.

Mr. CONABLE. Didn't I understand that your major point also was that the residence of the student was no reasonable criterion since these people went to college almost everywhere?

Dr. HAWORTH. That is part of it. The country mustn't lose the usefulness, the maximum usefulness of the very best people and the very best institutions.

Mr. MOSHER. Have we discussed whether the individual need and the economic need are factors in your selection?

Dr. HAWORTH. The individual need and the economic need are not factors.

Now, as to this other point that I was making—some of these successive steps have been involved in that, but in a little different sense. By the act, and I think appropriately, the fellowship holders are allowed to attend the university of their choice. The university does not have to accept them, but they are free to attend whatever university they prefer, provided they are accepted by that university. That means that graduate fellows tend to concentrate in a relatively few institutions. They all want to go to the best universities, of course.

In recognition of that tendency, the cooperative graduate fellowship program was instituted in 1959. The mechanism there is that individuals apply through the university that they wish to attend. The university then endorses them and comments on them, and so forth,

and the application is made. They are judged individually essentially, but then, of course, the awardees attend whatever universities they applied through. The result, therefore, as far as this group is concerned, is a much wider distribution of fellows among the universities than in the case of the "regular" graduate fellowship program.

If I can skip the teaching assistant program for a moment, I would like to turn to the traineeships. The traineeships were instituted in 1964 as a result of the studies of the Gilliland Panel of the President's Science Advisory Committee, in which there was concern about our ability to educate as many postgraduates, and particularly Ph. D.'s as possible, with the feeling that the country will need an increasing number. It was difficult to decide how many, but the Panel finally said, even though the ratio of students who would like to go into graduate school and get a Ph. D. in physics, engineering, or whatever, it might be, stayed constant, the growth in the number of students will be such that there had to be an increase of the sort that I spoke of the day before yesterday, in another connection. This will require an increasing amount of support, the Panel said, and, furthermore, there is unused capacity, in many graduate universities, for science and engineers, although some were perhaps overcrowded. So in response to that report we set up the traineeship programs in which the university itself applies, department by department, for traineeships, stating how many they think they can use, that is, how many students they can accommodate. These applications, then, are evaluated here in Washington not in terms of individual students but in terms of the judged quality of the department, the estimate of unused capacity, how much they could expand and still keep their quality up, and so on. And then we make grants for a specified number of traineeships to the university and the university selects the trainees.

This is why we call the individuals trainees as distinguished from fellows, who are selected by the Foundation in a national competition, although the general purpose, of course, is the same in both cases.

Mr. Conable. Doctor, to what extent do you decide how many trainees each college will get? They say what they think they can handle, is that it?

Dr. Haworth. In giving them the grant, we give them so much money for a specified number of traineeships and it is never as much as they ask for. In the first year we gave traineeships only in engineering. In the second year we gave them in engineering, the physical sciences, and mathematics, and we hope in 1966 or 1967, depending on funds available and so forth, to expand the program to include biology and the social sciences. The Gilliland report stressed the physical sciences and engineering, and especially stressed the need for more engineering support. Although we had hoped to start the traineeship program in all those fields, the first year our funds were not sufficient, and we decided, instead of scattering traineeships thinly across many fields, to concentrate on one field—engineering.

Mr. Brown. Can I ask at this point if you could provide just a little bit more detail in connection with these data as to the breakdown in the various fields that are covered—that is, physics, math, and so

forth—and the approximate ratio of the number that you are supporting as to the total number.

Dr. HAWORTH. Would you like for us to do it now or put it in the record?

Mr. BROWN. Either way.

Mr. DADDARIO. You may submit it later.

(The information requested is as follows:)

It is estimated that approximately 18,000 full-time graduate students in science, mathematics, and engineering will be supported in 1965 through the principal Federal predoctoral fellowship and traineeship programs administered by the Atomic Energy Commission, National Aeronautics and Space Administration, National Science Foundation, Office of Education, and the Public Health Service. Of this number, approximately one-third will be supported by the National Science Foundation.

National Science Foundation predoctoral fellowship and traineeship awards offered by program and field, fiscal year 1965

Field	Total	Graduate fellowships	Cooperative graduate fellowships	Graduate traineeships
Engineering (E)	2,206	273	296	[1] 1,637
Mathematics (M)	825	386	236	203
Physical sciences (P)	1,625	643	440	542
Any EMP fields	402			[2] 402
Subtotal	5,058	1,302	972	2,784
Life and medical sciences	453	343	110	([3])
Social sciences and psychology	431	289	142	([3])
Subtotal	884	632	252	
Total	5,942	1,934	1,224	2,784

[1] Of the 1,637 estimated awards in engineering, 712 were new traineeships and 925 "continuation" traineeships. A continuation traineeship is defined as a traineeship awarded in a previous year (fiscal year 1964 in this instance) under a grant to an institution and supported for another year from the current fiscal year (1965) funds. Although the institution may exercise some discretion in assigning continuation traineeships to fields being supported in the current program, it is the Foundation's expectation that the institution will normally continue the award in the same field in which the original grant was made.

[2] Of the 402 traineeships awarded to institutions in "any" EMP fields, it is anticipated that some will be assigned to engineering and others to the mathematical and physical sciences.

[3] In fiscal year 1964 traineeships were awarded in engineering only, and in fiscal year 1965 in engineering, mathematical, and physical sciences. In fiscal year 1966 the Foundation will make traineeship awards in the life, medical, and social sciences and psychology for the first time.

Mr. DADDARIO. The traineeship program would seem to both build up the quality of the school and to train people whom you might not otherwise have an opportunity to even know about?

Dr. HAWORTH. That is right. To give you an idea of the impact, we gave grants in 1964 to 109 universities—that is, graduate engineering institutions, and that represented nearly all the ones in the United States that give Ph. D. degrees. That is a criterion for eligibility, that they give Ph. D. degrees. This year, 163 institutions received grants, the same ones, and additional ones. This gets to be a pretty big fraction of the institutions that give Ph. D. degrees in science.

Mr. DADDARIO. It seems to me it would help the record if we could get a list of them.

Dr. HAWORTH. We can give you a list showing the breakdown of where all these people go.

1/ In fiscal year 1964, the first year of the Traineeship Program, awards were made in engineering only to 109 institutions; in fiscal year 1965 awards were made in the engineering, mathematical, and physical sciences to 163 institutions. Of the 2,784 traineeships awarded in fiscal year 1965, 1,859 were for new and 925 for "continuation" traineeships. A "continuation" traineeship is defined as a traineeship awarded in a previous year (fiscal year 1964 in this instance) under a grant to an institution and supported for another year from the current fiscal year (1965) funds.

Dr. HAWORTH. The graduate teaching assistant fellowships are awarded for study and research in the summer to students who are part-time teachers in the academic year. They receive stipends for only the summer months.

Chart 19 (p. 70) gives an idea of how many institutions we are reaching in all our programs. The total of 914 is not the sum of the numbers participating in individual programs because many institutions receive funds in more than one category. This total of 914 institutions is out of a little more than 1,000 universities and colleges granting some kind of a degree in science or engineering.

Chart 20 (p. 71) gives an idea of how our research support funds are distributed among the nine geographic divisions. Funds for facilities are omitted because when only 1 or 2 years are being considered, the inclusion of facilities data creates a distortion since a particular facilities grant may be large compared with the total for the year.

Here, as you can see, the left-hand bar is the amount of NSF funds granted in a particular region—the east north-central region and the Middle Atlantic and so forth—in percent.

The second bar represents in each case the percentage of all doctoral degrees in science and engineering, awarded in the college year 1963–64, to the geographic division in question.

CHART 19

The next bar is the percentage distribution of total degrees in science and engineering, including bachelors, masters, and doctorates, in the same year; and finally, the fourth bar is the distribution of high school graduations for earlier years. We don't have the statistics for 1963–64, but that doesn't change the picture. We have, as you know, the three national centers, one in Arizona, one in West Virginia, and one in Colorado. Of course, they and the Mohole project are visible things and affect NSF geographic statistics, so the left-hand column for NSF has been broken down into two parts for several divisions. The top darker part represents the expenditures at a center and the bottom part represents all the rest. Only three regions are affected that way.

The chart gives an idea of how NSF support is related geographically to various educational factors. There is obviously no yardstick that is a correct yardstick, but these certainly—the number of doctoral degrees, the number of other degrees, the number of oncoming students—are certainly pertinent to the situation.

Mr. VIVIAN. I am very curious about that chart, having looked at it at some length. It seems to show that as you move west toward the Mississippi Valley region the ratio between column No. 1 and column No. 2 changes, and then it improves again as you move toward the Pacific coast. Is this because the States in the central part of the Nation have a higher level of State financing for their operations or not?

Dr. HAWORTH. There may be some impact of that sort certainly with respect to the east. I would be surprised if it is true as compared to the west coast, where there are the University of California and others. The factor is there, as you have said, there is no doubt about it.

CHART 20

Mr. VIVIAN. It is a ratio of about one and a half to one.

Dr. HAWORTH. It is in the research support, not the education support that this comes about, and it results from the fact that our research grants are given on the basis of quality, and there is, of course, a relative concentration of the very best universities in New England, in Middle Atlantic, and California. This does not mean that there aren't as good ones in the Middle West, but the portion is very high in New England. MIT is there, Harvard is there, Yale is there, and so on. This does result in the effect that you have pointed out. The other thing, of course, is that the number of Ph. D.'s actually produced in the Middle West is very large. There is no question about that. On the other hand I hasten to point out that of the 10 universities that get the most support from the Federal Government, 5 are in the north-central region. They are Chicago, Illinois, Wisconsin, Minnesota, and Michigan.

Mr. VIVIAN. Why do you feel they turn out so many Ph. D.'s there? Is that an aberration?

Dr. HAWORTH. They are large schools; I suppose that is part of it. The big 10 State universities are big institutions. These are National Science Foundation figures, but the geographic effect is similar for the total of all the agencies. In fact, this effect does not show quite as much with NSF as it does with the total of all the other agencies, because our funds are distributed a little more broadly than others. This is, of course, the so-called geographic distribution question. This is one of the reasons why we have the science development program.

Mr. VIVIAN. You indicate this is primarily in the support of research rather than education as such?

Dr. HAWORTH. That is right.

Mr. VIVIAN. You have another chart which showed a relative uniform distribution with respect to education. I think that is the one you have in front of you there?

Dr. HAWORTH. This chart 21 shows one aspect of education, the fellowships.

Mr. VIVIAN. They were relatively proportioned, I believe?

Dr. HAWORTH. That is correct. There is no one index that is appropriate for all comparisons, but the one we have here is the distribution of NSF fellowships: in the first column, all NSF fellowship awards; second, the fellowships that are given by the national competition; third, we have the distribution of doctoral degrees earned by residence of high school graduation; and finally the percent of all male graduate students who reside in the area. We used male rather than total because most science, engineering, and mathematics graduate students are men. Women tend to concentrate in other fields. If we included the women, it wouldn't be as good an index for this purpose as the men.

Mr. VIVIAN. Do I interpret your remarks correctly as follows: That the larger institutions in the Midwest are turning out a large number of students, and those are generally the ones that turn out doctorate degrees, and that these are fairly heavily supported from NSF. It must be, therefore, that the smaller school in the Midwest are not doing relatively well compared to the smaller schools in the East and the West?

CHART 21

Dr. HAWORTH. I can't quite agree with your last remark, although, as I said, 5 of the first 10, in terms of support, are in the north-central region. There are other large institutions in this region that aren't in those five, of course. Certain ones who are getting support in California, for example, are also large institutions. The ones that are getting the most support in New England and the Middle Atlantic are not as large as Illinois and Michigan, and so on.

Mr. VIVIAN. I am in no position to be regionally biased in remarks relative to your second chart, chart 21. It seems to be very closely tied to the awards. But I am interested in knowing the explanation as to why the support ratio is so low on chart 20.

Dr. HAWORTH. As I say, it is the result of the concentration—the relative concentration of the best scientists and so forth in the northeast and Pacific regions. I am very careful to say relative, that is, that—Harvard, MIT, Stanford, Berkeley, on a smaller scale, Cal Tech, and so on are in those regions. Incidentally, this north-central region is my home, too.

Mr. VIVIAN. I know.

Dr. HAWORTH. So I am personnally concerned about it, too. It is what has happened as a result of the merit system. One must remember, of course, and I say this very earnestly, that these schools that are getting this support were good schools long before there was any Federal support. Federal support didn't make them this way. This is the way they are.

This is one of the important considerations that makes us want to have the science development program.

Mr. BROWN. Would it be also possible to interpret this as indicating that there may be a substantial immigration of Ph. D.'s from the central area to the coastal areas?

Dr. HAWORTH. There undoubtedly is that immigration. What impact that has on this particular thing I am not sure. There is certainly an immigration from the North Central region to both coasts. It is immigration in two senses: One, stimulated by the location of industrial research and development, and, two, influenced to some extent by in-house Government research and development which tend to be concentrated in other places than the North Central region.

For example, offhand, I don't think of any large Government-owned research laboratory in the North Central region except the Argonne Laboratory of the AEC in Chicago.

Mr. BROWN. I think that is correct. Of the eight major accelerators, only one has been built in the Midwest, and that is the Argonne accelerator.

Dr. HAWORTH. I am thinking also of Los Alamos, the Jet Propulsion Laboratory, and so on. There is one other in-house laboratory in the North Central region, a large one at Wright Field. There is undoubtedly an immigration of Ph. D.'s in that sense. I don't think it is so true any more, but in past decades there was a tendency, even in the academic world, for the best ones to leave the central part of the country and go, first, primarily to the east coast, in the next stage, to both the east and the west, but now they are staying home more. It is those best ones that migrated very long ago who are partly responsible for the fact that grants tend to be concentrated now on the east and west coasts.

Mr. VIVIAN. Do you have any yardstick on performance, in terms of quality of education, which would apply at the bachelor's level or the master's level? I don't imagine there is any qualitative measure at the Ph. D. level which would allow you to determine the relative quality of the various institutions across the country?

Dr. HAWORTH. There is certainly no really objective yardstick. It is a subjective feel that each individual has who knows the situation.

Mr. VIVIAN. At the high school level you have the various high school testing systems.

Dr. HAWORTH. Yes, that is right.

Mr. VIVIAN. Do they indicate any relative difference in quality across the country?

Dr. HAWORTH. Some, but it is awfully hard to tell whether there is any innate difference at all.

Mr. VIVIAN. I am referring only to the effectiveness of the education given the students.

Dr. HAWORTH. There are certainly substantial differences in the effectiveness of the education given through high school.

Mr. VIVIAN. That shows up?

Dr. HAWORTH. Yes.

Mr. VIVIAN. Where would that show at its lowest and highest points?

Mr. CONABLE. We have already talked about New York State's problems.

Dr. HAWORTH. High school educationwise, New York State has some very good and some very bad.

Mr. VIVIAN. I am just trying to track down the question as to whether the quality of education is a factor, as well as the height of some of those bars on the chart, and if it is a question of rising through the various levels of education.

Dr. HAWORTH. The quality certainly varies. It varies locally, as we all know; it varies regionally. The differences regionally are not always due to the difference between school districts.

Mr. VIVIAN. For example, is a Ph. D. or a master's degree from a Midwest school considered to be as good an educational experience as, say, from the two coastal areas?

Dr. HAWORTH. From the best ones, yes.

Mr. VIVIAN. Then, there is no obvious reason why the support ratio should be off by a factor of $1\frac{1}{2}$ to 1?

Dr. HAWORTH. We have to take into account the past as well as the present. I know time is fleeting, but could I spend 3 minutes talking about my own experience with respect to this problem?

Mr. DADDARIO. You certainly can, Dr. Haworth.

Dr. HAWORTH. I got in the business of science and science education awfully long ago; I graduated 40 years ago from college, so I have watched it for a long, long time. In the first place, this country hadn't been doing academic research on any appreciable scale for very long in the 1920's, it was primarily a European activity, but there were a few American universities who were beginning. Some had been doing it for quite awhile. There was Harvard, Yale, Princeton, Columbia, and so on, who were the leaders in the East. In the Middle West there were only three that were doing any appreciable amount of research across the board, although others were

in some fields. Those three were Michigan, Chicago, and Wisconsin. For example, there was good chemistry at Illinois, but there was practically no research in physics. I graduated from Indiana, and in those days there was virtually no research at Indiana. On the west coast, when I graduated from high school, Cal Tech was not well known, there was little or no research there; it was known as the Throop College of Technology. In 1921 they got R. A. Milliken as president. Milliken was a Nobel Prize winner and he was a very great physicist. He decided to go there and build up this institution; the name was changed about the same time. He began to get new people, and by the 1930's, about 15 years after he went there, this had become a small but very high quality institution. It had some very good people. That is one of the points I wanted to make. It is really people and ideas that make these things.

Berkeley had not been up to that time a very thriving center, but there were some people like Lewis in chemistry and Ernest O. Lawrence, who went into physics in the late twenties—who invented the cyclotron and so forth—who built that up. Some good people went to Stanford at about the same time. So the west coast began to build up. In 1928 Karl Compton became president of MIT, which had been just what its name implies, a technological institute, and an excellent one. But it was not a research institution or a graduate institution in anything like the sense it is now; it began to build up and by World War II it had become this kind of an institution.

At Illinois—and I have to speak mostly of physics and chemistry, mostly physics, a little of chemistry and math, because these are the fields that I have had personal experience in—in 1928 in Illinois they brought as chairman of their physics department, Dr. Loomis, and by the end of the war they had a very good department, and Roger Adams brought in very good people and built up one of the finest chemistry departments in the country.

Wisconsin kept building up. One of the important things there was that Dr. Steenboch devised the scheme of irradiating milk to get "vitamin D milk," and the Steenboch patent was turned over to the university. They founded the Wisconsin Alumni Research Foundation, and the income from just that patent—other patents were added but that one had widespread application of course—provided lots of funds and the university went ahead rapidly in research.

So there has been a constantly growing number of new places. But all the ones I have mentioned grew on their own before the war. Well, the process has continued, but the highest of the high spots throughout these regions, as I say, started in the East and in the West and a little bit later in the East North Central area.

Mr. VIVIAN. I think if I were to ask you to draw another bar which would show the number of Nobel laureate awards, it would be very high on the California side.

Dr. HAWORTH. Yes, it certainly would.

Mr. VIVIAN. If you were to draw another bar on there which would show where they gained their doctorate degrees, do you think that would be uniformly spread or not?

Dr. HAWORTH. I suspect it would. I think you would probably have to make an average differentiation. Are you talking about the Nobel laureates?

Mr. VIVIAN. I am referring to where the Nobel laureates received their training.

Dr. HAWORTH. I think they would still concentrate in the East and the Far West, but not so much among the younger ones as the older ones.

Mr. MOSHER. Mr. Chairman, I suspect it would be an interesting study of some significance to know where some of these men got their original inspiration in undergraduate work: For example, Milliken at Oberlin, Compton at Worcester, there are certainly undergraduate schools that have had a big influence.

Dr. HAWORTH. Yes, there is another one out in the Dakotas, where Ernest Lawrence and two or three other famous scientists were undergraduates. In fact, there is one high school that they went to.

Mr. DADDARIO. When Mr. Vivian asked you about the Nobel Prize winners, where they got their training, I thought I heard someone in the audience say half of them would probably be from Europe.

Dr. HAWORTH. No. I have forgotten numbers, but before the war, of course, most of the Nobel Prize winners not only got their training in Europe but they also lived in Europe.

Mr. DADDARIO. The actual number is not so important.

Dr. HAWORTH. Actually only on the order of 10 percent of American Nobel Prize winners came from Europe. It used to be true. An interesting thing is in the last 12 years exactly half of the Nobel Prize winners in the sciences have been Americans, and of those Americans I think about 10 percent were born in Europe.

Mr. BROWN. Following up on this very interesting discussion you made about the spread in the development of these outstanding institutions, haven't we seen a continuation of that phenomenon within the last few years?

Dr. HAWORTH. Oh, yes.

Mr. BROWN. Developments have taken place in Texas and in other places in the South. Isn't that really what we want to encourage?

Dr. HAWORTH. Yes. It has kept going, the same thing. There are more and more good institutions. I confined myself to the prewar history because there was no Federal fund influence then. It has kept on. There are many very good institutions now. They still may not have caught up with the leaders, but they are at the stage that the leaders were not terribly long ago. For example, in the State I grew up in, in Indiana, Indiana and Purdue are now both very good graduate universities. To Michigan has been added Michigan State, and Wayne is getting to be a very good place. I am speaking now of the larger ones. Minnesota I wouldn't have mentioned back in the 1920's or 1930's as one of the leading ones, but it now is. You can say the same thing in other areas of the country.

Mr. VIVIAN. I wonder if I could ask you to provide me for the record a similar chart showing the distribution of funds for the training of students up through the high school level and the training of their instructors. In other words, I would like to limit the subject strictly to the training that terminates at the high school level for both the students and the instructors.

Dr. HAWORTH. You are speaking of the support for this?

Mr. VIVIAN. Yes.

Dr. HAWORTH. We will be glad to give this. I would like to point out one thing, that in terms of the effect on the students—well, even the teachers—such a tabulation is not necessarily too meaningful for the following reason. A college in Tennessee may hold a teacher's institute in the summer but draw its students from many States, and we have no knowledge of that. That is, not the students, but the teachers attend the universities, so the teachers are affected and, in turn, the high school students that are affected are not necessarily distributed in the same pattern as the funds given to the institutions. We will be glad to give the information, but you must bear that in mind when you study it.

Mr. DADDARIO. Would you supply whatever you can for the record.

(The information requested is as follows:)

NATIONAL SCIENCE FOUNDATION

PERCENT OF TOTAL SUPPORT BY REGION FOR ELEMENTARY & SECONDARY SCHOOL TEACHERS & STUDENTS (FY 64 & 65) COMPARED WITH ALL GRANTS TO COLLEGES & UNIVERSITIES FOR EDUCATION IN SCIENCE, FY 1964, & TOTAL POPULATION, 1963

NOTE - All numbers in parentheses are the percent of the total.

Mr. Roush. A couple of years ago, maybe 3 years ago, an official of the Defense Department made a statement in Chicago that one reason there was not a more equitable distribution of Federal support funds for research, development and procurement was that there was an "intellectual vacuum" in the Midwest. That is the reason the Midwest was neglected. This was echoed again by the Secretary himself. Your chart wouldn't indicate that. Would you care to comment?

Dr. Haworth. I wouldn't agree with that statement. What I am about to say has nothing much to do with the NSF, but I would like to comment just a minute on this broader problem, and that is, of course, the largest concentration of funds away from the Midwest, if you want to put it that way, or on the two coasts, is not in research funds or in academic funds but in development funds. The electronic business in New England, and the aerospace business on the Pacific coast, for example, are actually, in my opinion, simply the result of past history. Part of the Middle West and as a matter of fact parts of the East were the mass producers long before the war, the mass producers of consumer goods; the automobile industry, the steel industry and so on. During the war the mass production of armaments was done in the Midwest. Look what Detroit and Willow Run did in the way of tanks and airplanes and so on. The heaviest concentration of R. & D. was in New England and on the west coast, and there wasn't much in the Middle West because they were doing the other armaments job. At the end of the war the Middle West, and I am saying the Middle West just because this seems to be the place that we have talked the most about, reconverted to the production of consumer goods, appropriately so.

New England happened to be a region that was losing some of its old industry, the textile industry, and so forth. On the other hand, it had been a place for concentration of certain activities—the radar development at MIT, the countermeasures development at Harvard, and things of that sort. Individuals who went there during the war stayed there afterward. They liked it there and they set up their little companies.

Then in the region around Stanford University, there was a very strong electronics group. The Klystron was invented there before the war by Bill Hansen. It had Fred Terman, who is an outstanding electrical engineer. And the same sort of thing tended to happen there. This really goes back to prewar and wartime history. There still is great production in the Midwest. The Federal Government certainly buys lots of things from the Middle West. I think actually the difference is in industry and not in the universities.

Mr. Roush. Dr. Haworth, I have been interested in this matter of geographic distribution, trying to avoid being provincial even though I am from the Midwest. It has seemed to me that it is in the national interest that we consider this problem. Of all the agencies of the Government which really have contributed to a geographical distribution of Federal funds in research, I think your agency has done the most. I think this is due to a couple of reasons. One is your funds go to basic research, where we do not have the question of mission being considered. Secondly, and what I think is most important, is that this was part of the intent of Congress when the National Science Foundation was created.

In reading the background material for these hearings, it appears that there has been a gradual and perhaps unconscious turning from this admonition, slight, perhaps, but still it is there. It seems to me the point raised by Mr. Vivian gives credence to this thought and indicates that perhaps you now are contributing—and it is beginning to become significant—to the concentration of research and development on the two coasts by reason of the funds ratio shown on this chart as compared to the degrees awarded at these various institutions.

Dr. HAWORTH. I can't find any evidence that the NSF distribution is any more concentrated now than it was. In fact, what little evidence I can find, going back far enough to be significant, is that it has been going the other way. It certainly has been spreading out among institutions. That, of course, you can expect. The first year NSF only had a small sum of money. If you only had a hundred thousand dollars, you might give it all to one university, but if you have a hundred million dollars you are obviously going to give it to more than one university. So the larger the support you get, the more it is going to spread. I fully subscribe to all the implications of your remarks, as I said before, but the Midwest is not the only place in question. For example, what we need to do in the South for the good of that region and the good of the country, is very important.

Mr. ROUSH. I thoroughly agree with this. But if your awards are made solely on the basis of merit, it is only natural that these people who have great competence in those fields will migrate to those areas where there is presently an outstanding competency on the part of the universities or industry. Therefore, it will be only natural that your funds will go to those areas if this is the main criteria of your awards; isn't this true?

Dr. HAWORTH. There is certainly going to be some of that, but that is precisely why we are trying to have other programs that counteract this tendency. Frankly, in a given research program conducted by the Foundation, I don't see in awarding, say, 25 grants out of 50 applications how we can balance the question of reasonable distribution against the question of merit within that program. I believe we should have two kinds of programs, one of which is purely a merit program and the other of which is avowedly to build up strength in certain places.

Mr. WAGGONNER. When that second program starts achieving its purposes——

Dr. HAWORTH. They begin to compete.

Mr. WAGGONNER. I think the charts are misleading because we are talking about dollars and cents as related to the number of degrees awarded. This is misleading because you get a picture which does not relate to the total number of people that we are talking about.

Dr. HAWORTH. You mean the total population?

Mr. WAGGONNER. The total population as such. There is a direct relationship. For example, geographically speaking, we have some small areas but we have mass concentration of population. In other places we have big areas but it is sparsely populated. We have to relate all those factors to get the picture here. The thing that is deceiving when you look at the bar chart, one looks small and the other looks large, and it distorts it.

Dr. HAWORTH. The question here, of course, is the chicken and the egg, and I am not giving any implication in stating the question: Is the National Science Foundation the one to build up stronger high schools, stronger grade schools, a tendency to go to school at all in various regions of the country, and to what extent should it, on the other hand, put its funds where the strength already is? What I am trying to say is I think we have to look at it from both sides, look at it with both eyes, and I think you have to keep the two objectives somewhat separate.

Mr. WAGGONNER. This is the reason we have to have two programs, as you say.

Dr. HAWORTH. That is right. Now, the President's general education programs, of course, are directed at the business of building up the general level of education and attainment and so forth throughout the country. That is still another aspect of it.

Mr. WAGGONNER. After all, it is impossible for you to accomplish anything no matter how good your program might be if you do not have some initiative and some cooperation from the people back at the grassroots?

Dr. HAWORTH. That is right. And all of these places that I spoke of earlier that are good institutions—and I hope anybody whose institution got left out will realize there are a great many good ones I didn't mention—all of these institutions built up on their own. Sure, since the war, they have received Federal support, but earlier it took initiative, good ideas, and people who wanted to build the institutions.

Mr. WAGGONNER. New England and the Far West are good examples of that.

Dr. HAWORTH. That is right. They are good examples. Of course, they have had the tremendous growth of students. The place where the East has lagged quite frankly is in public universities.

Mr. WAGGONNER. Facilities in public universities?

Dr. HAWORTH. That is right.

Mr. WAGGONNER. They haven't expanded their facilities as other areas have?

Dr. HAWORTH. That is right.

Mr. VIVIAN. Dr. Haworth, 2 days ago you stated you were following a policy, roughly as follows: If you came to a situation where two proposals were roughly equal in quality, that you would tend to give preference to that proposal which was from a geographically less well-off area. Is that a correct restatement or not?

Dr. HAWORTH. I actually make that statement about the fellowship programs. I have to say it a little differently for the research. We tend to think of it this way. There are really three things. We have to maintain the quality of the best institutions and give them good support, in the first place, in order to get good research done, and in the second place, in order to educate the high quality students that go there. Incidentally, it is very important to the universities all over the county that good people come out of Harvard and MIT and so on. Such institutions are the wellsprings, the sources of the best people. The second thing is we have to have more good institutions wherever they are. The third thing—and I don't put any order of priority here—is that as we build up institutions, let's build them up so that all regions of the country have good institutions.

In the first instance, when our funds were small, the distinction was probably made institutionally rather than regionally, but more and more it is being made regionally as well as just institutionally. Other things being equal the aim is to spread funds among more and more institutions.

Mr. VIVIAN. Does that suggest if we appropriate more funds for NSF next year you will spend more in the Midwest?

Dr. HAWORTH. There would be more everywhere.

Mr. VIVIAN. That isn't the way I worded the question.

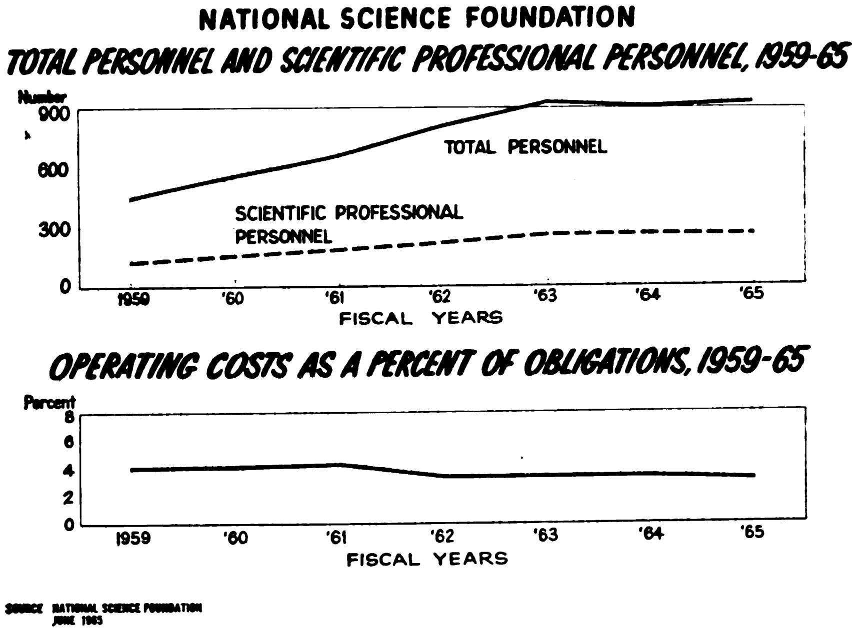

CHART 22

Dr. HAWORTH. Chart 22 is one I thought you might be interested in. It shows how much we spend inside the Foundation for administration. It simply shows the level of total personnel and of scientific and professional personnel over the last 6 or 7 years and the operating cost as a percentage of the obligations. It has actually gone down a little bit.

I think maybe it would be better if you permitted me to read this last statement and to bring in the last two charts at the appropriate place in the statement. You remember that this was the sequence I suggested we follow the first day.

Mr. DADDARIO. I understand the statement you are reading now is the one dated June 24.

Dr. HAWORTH. Earlier in this presentation I have attempted to give you a reasonably complete understanding of the Foundation's present place in the Federal science-support complex, and to tell you what we have been and are at present doing. Let me now try to place NSF in the Federal science structure of the near and long-range future.

Let us briefly analyze the present situation. The lifetime of the Foundation has been a relatively brief span of 15 years. This has been a period of great growth in American science and, relatively speaking, of even greater growth in Federal sponsorship of that science. Just as in research, the methods of support, the relationships with non-Federal institutions and many other aspects of methodology had to be explored. Especially in the early days, attention had to be devoted to those areas where support was crucial to the immediate progress of the country. Many techniques and policies were tried, most have been successful. Inevitably the advances have been made by driving salients—all of them important. Equally inevitably, some fronts have lagged behind.

As this committee has wisely seen, now is a time for retrospection and consolidation—to view the campaign as a whole, to plan the future strategy, to look to the longer range objectives. In what follows I shall attempt to call attention to some of the factors that may be involved.

As time moves on, I see NSF accepting a heavier financial responsibility on behalf of all Federal agencies for an expanding basic science. I believe that all agencies should and will continue to support basic research, as they now do, but NSF is likely to be thought of as the logical agency to meet a major fraction of new and expanding requirements.

There is wide agreement that Federal support of scientific research should expand, particularly in the universities. A substantial portion of the basic research conducted in the United States is carried out by professors and other scientists at such institutions. As you all know, this research is particularly important to the future of the country for two principal reasons: first, most of the research performed at academic institutions lies at the frontiers of scientific knowledge and thus is most likely to contribute to the strength of our science and technology in the long run; second, such research is an essential ingredient in training future scientists and engineers—both because student participation in research is essential at the more advanced levels of education, and because research stimulates and improves the facilities.

In recognition of these facts the President, in his budget message to the Congress this year, called for an appreciable increase in support of academic research. Furthermore, he assigned a special responsibility to the National Science Foundation for providing an increased proportion of Federal support for such research. The Congress has consistently supported academic science; as a recent example, in our appropriation bill passed last month, the House of Representatives explicitly endorsed our efforts to increase the number of centers of scientific excellence throughout the country, thereby reaffirming the importance of strong programs of support in educational institutions. The recent report submitted by the National Academy of Sciences to the Committee on Science and Astronautics, stresses the requirement for an expanded Federal effort in the support of basic research. Thus, there is general agreement in the executive branch, in the Congress, and among representatives of the academic community that the Federal Government must continue to assume a major share of the responsi-

bility for adequately supporting basic research in institutions of higher learning, including provision for an appropriate rate of growth.

The need for increasing support arises from three causes: first, many first-rate scientists are not now given support adequate to permit them to reach their full effectiveness; second, support must be provided for increasing numbers of faculty members and graduate students as academic institutions expand their enrollments to meet national needs; it is estimated that this increase will be some 8 or 10 percent per year, for many years to come. Finally, we must provide for the fact that the cost of research per scientist constantly increases, primarily because the growing complexity of research required the use of more sophisticated equipment and additional supporting personnel. The annual increase in cost per scientist is estimated at some 5 to 7 percent.

If we combine these estimates, we find that each year we will need an overall increase of 15 percent or more in support of research in academic institutions merely to maintain a constant relative level of research effort in those institutions—to hold our own, so to speak. Because we recognize fully the imprecise nature of this 15-percent estimate, constant efforts are being made to discover better ways to determine these future needs. For example, consideration of this problem will form an important part of a study of basic research, particularly at the universities, which will be carried out this summer by a panel of the President's Science Advisory Committee. This study is regarded as a significant step in a continuing effort to understand and analyze these problems. The Foundation is partaking in and is providing a major component of the staff work for this effort.

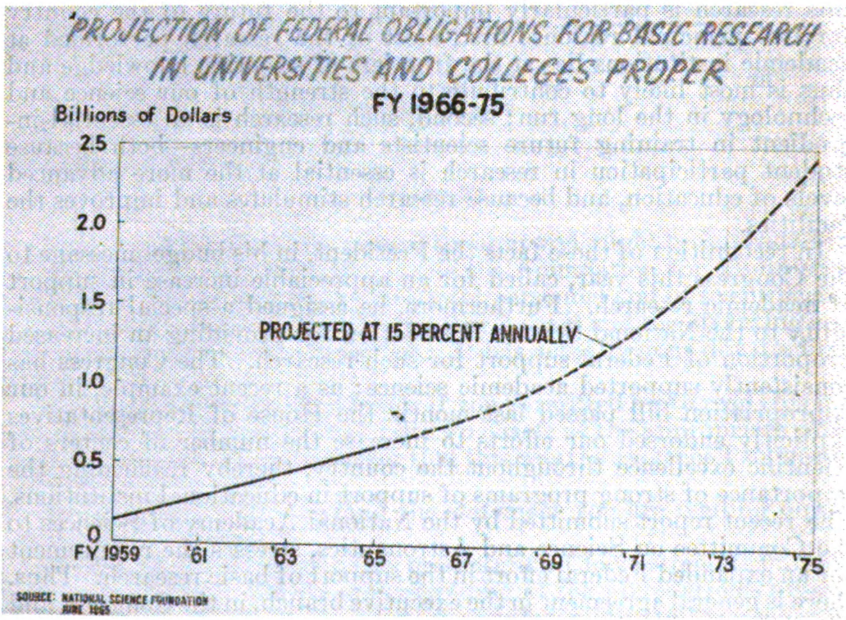

CHART 23

NATIONAL SCIENCE FOUNDATION

PROJECTION OF NSF OBLIGATIONS FOR BASIC RESEARCH IN UNIVERSITIES AND COLLEGES PROPER

1966-75

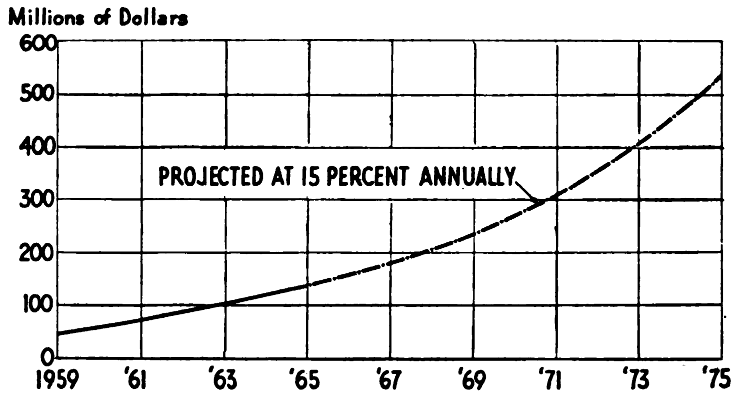

CHART 24

Here is where I might stop and allude to charts 23 and 24. These charts give you an idea of what the future would hold if the Foundation and the Federal Government, as a whole increased academic support by 15 percent annually. The Foundation is engaged in basic research with only one or two exceptions, but the Federal support of basic research in universities and colleges is just about half the total Federal support of research and development in universities and colleges.

Mr. WAGGONNER. Will this 15-percent annual increase change that ratio?

Dr. HAWORTH. I see no reason to think so because actually the 15 percent I alluded to is meant to be a rough estimate of the rise in support of research needed in colleges and universities, be it basic or applied. I see no reason to expect any change in the ratio of basic to applied research. At this time the Federal basic research support in chart 23 represents about half of Federal research and development support to colleges and universities. A large fraction of the support is by NIH. As I recall, NIH classifies about 60 percent of their support as applied. You can see if this rate of increase were indeed followed—I make no claim, as I have said, for any precision in this estimate, but it is just some kind of a guideline—Federal basic research support at universities proper would reach nearly \$2½ billion 10 years from now.

Chart 24 shows what would happen if NSF maintained a constant fraction of the Federal total in chart 23. Then NSF support in universities and colleges proper—again when I say proper, I leave out the contract research centers—would grow from its present level of about \$130 million to a little under \$540 million.

Mr. DADDARIO. Do you base that raise on the percentage of your growth to this date?

Dr. HAWORTH. This is just using the analysis of support that I read while you were out of the room. It is also the same one that Dr. Brooks has in the Academy report to the committee. It is estimated that the number of students and therefore the faculties will have to increase about 10 percent each year and that the cost of doing research because of its increased complexity, the use of computers, etc., goes up about 5 percent per year. So as a crude guideline one might estimate that to keep things going as they are in the universities it would take at least 15 percent per year even if support were adequate now, which I don't quite concede. So the 15-percent rise is not necessarily related to the past, although for the total Federal Government it is in the same ball park as in the past.

Mr. DADDARIO. What do you base the 15-percent estimate on? What is your beginning point?

Dr. HAWORTH. Let me talk about the total Federal support.

Mr. DADDARIO. I am referring to the total Federal support for the moment.

Dr. HAWORTH. The oncoming wave of students which hasn't hit the graduate schools yet is going to cause rises in enrollment of 8 to 10 percent each year for many years.

Let's assume that about the same proportion go into graduate school as now, and of those the same proportion go into science and engineering and mathematics—actually that proportion is increasing a little bit or has over the past 15 years; it goes up and down. Let's assume that we have to have a proportionately larger faculty to take care of these students. Then this means that at the graduate level the universities will grow about 10 percent per year. So if you are going to give support to the students and faculty in the same degree that you are now, that would call for a 10-percent rise. However, research continues to cost more and more. I am not now thinking of inflation in the usual sense, but just that research gets more expensive as it gets more complicated. It takes more complicated equipment, more people to run the machines, and this is estimated to account for from 5 to 7 percent. So taking the 8 to 10 percent, on the one hand, and the 5 to 7 percent, on the other, you come to the combined figure of about 15 percent. It is crude, but it is a guideline.

Mr. WAGGONNER. It is a guideline to maintain the present support without closing the gap?

Dr. HAWORTH. That is right.

What has been happening recently is that the mission-oriented agencies have not been increasing their support of university research, or of basic research generally, as rapidly as they did in the past. They are going up, only about 10 percent. This is determined by the needs of their missions because they do not have a direct responsibility for the universities and colleges as we do—that is, agencies such as the Defense Department and the AEC do not. They all do their best, but their missions have to take first priority. So, since they are going up only about 10 percent, if the total is going up 15 percent, we have to go up more than 15 percent.

As a matter of fact, in constructing the budget this year, this was all taken into account. The amount requested in the NSF research budget, the one before the Congress, the budget for 1966, was held undetermined until the last minute, until the budgets of the other agencies, NIH, DOD, AEC, and so forth, had been more or less finished. Then the situation was analyzed to see how much shortfall there was going to be with respect to the curve of chart 23. The necessary increment in NSF's support was calculated to be about 15 percent on its own previous support, plus the shortfall in the other agencies, estimated at $50 or $55 million. So the President's budget included that extra amount in the NSF budget in order to make up for the fact that the other agencies were not going up as much as was deemed necessary to support the research in the academic institutions. That was the detail of what I referred to in my prepared statement.

I have actually, Mr. Chairman, just said in more detail the next paragraph in my written statement, so I won't take time to read it. We will go on to the first paragraph on page 5.

In stressing the importance of research in academic institutions and the need for it to grow, I do not mean to neglect the important role played by the national research centers. They must continue to be supported and their programs should be strengthened and expanded. Perhaps from time to time there may be occasion to establish more of them in special fields. For example, I expect that, once it reaches the research stage, Project Mohole will be operated as such an activity.

These centers are national because they serve the Nation in several ways. They provide centralized resources for the conduct of research—including specialized equipment and scientific services that are beyond the scope of most universities. Scientists from institutions throughout the country may freely avail themselves of these resources and may, in fact, work jointly with the permanent center staff on continuing research problems. Thus the centers are essential both to the effective advancement of science and to the health and vigor of the traditional institutions engaged in such research. An important feature is the opportunity they provide for graduate students and especially young postdoctoral scientists to undertake advanced study and training.

Let me turn now to some important questions regarding the nature of our support at academic institutions. The first of these might be stated thus:

How and to what extent can individual higher education institutions, as a whole, be most effectively strengthened by Federal support of research?

It is essential that these institutions indeed be strong. Although each is dependent upon the individual talents of its faculty, those talents flourish best in a vigorous environment—one that stimulates intellectual achievement and provides the means for such achievement. In a very real sense institutional strength can provide a situation in which the whole is greater than the sum of the parts. Furthermore, without such strength the institution cannot retain the services of the outstanding individuals on which success depends.

Let us look at our methods of research support in the context of this question. The project system had its origins in the fact that the mission-oriented agencies with a desire to support research in their own fields of interest provided the early postwar support. They received proposals for specific programs of research and judged them individually. As I have said, the Foundation has used this system from the beginning and—in common with some other agencies—incorporated the help of advisory panels.

This system of "judgment by the peers" turned out to be a great invention. It brings into the evaluation process the most highly qualified scientists in the country and is, furthermore, a protection against the possibility of errors in judgment that might result were programs determined by a relative few within the Government who were not in immediate and constant touch with progress in the various fields.

This system is still sound, useful and vigorous. We will have it with us for a long time to come. Individual scientists generally favor it over any alternative method thus far put forward. Its disadvantages are recognized, but its advantages are far more weighty.

Mr. VIVIAN. I have a question relative to the "judgment by peers" approach, which you are following and which I personally regard highly. Is the same system utilized to a significant extent by other agencies who are granting research contracts and grants?

Dr. HAWORTH. NIH has essentially the same system, in some sense a more formalized system than we do. Other agencies use it partially. The Atomic Energy Commission does not use it at all, in this same sense for judging individual proposals. As I understand, it is used in some places in DOD.

Mr. VIVIAN. You have left out NASA.

Dr. HAWORTH. I don't believe NASA uses this system.

Dr. WILSON. NASA has some committees similar to our divisional committees but no committees at the panel level.

Dr. HAWORTH. All the agencies have advisory committees, but I am talking about the actual selection of proposals.

Mr. VIVIAN. You would say your agency and NIH use it heavily, DOD to a moderate extent, and AEC and NASA to a very slight extent?

Dr. HAWORTH. I don't know to what extent Defense uses it.

Mr. VIVIAN. Has there been any informal exchange between these agencies on this system to allow the people in charge to be relatively exposed to your procedure?

Dr. HAWORTH. They are all very aware of it. There certainly haven't been formal exchanges in recent times.

Mr. VIVIAN. Do you have any documentation to indicate why other agencies use it far less than you do?

Dr. HAWORTH. I haven't.

Mr. VIVIAN. Mr. Chairman, I would like to inquire into that subject further with the other agencies.

Mr. DADDARIO. There is no reason at all, Mr. Vivian, why we can't pose questions to them either in writing or when some of their representatives come here.

Mr. VIVIAN. As a basic matter in support of science in which all these agencies are dealing, I would like to know what their reactions are to this.

Mr. DADDARIO. We have a list of witnesses covering all the agencies.

Mr. CONABLE. Mr. Chairman, I understand NSF grants are considerably more prized than those from most other agencies, including the NIH. Is there any reason for this? Is it that your system carries with it a little more prestige?

Dr. HAWORTH. I think that what Mr. Vivian was talking about, the panel system and so forth, has created a feeling that the award of an NSF grant, or an NIH grant as far as that is concerned, indicates that the proposal was highly thought of by the scientist's own colleagues and this affects the man all right. I don't know of any other reason.

Mr. CONABLE. Why would there be any difference between NIH and NSF?

Dr. HAWORTH. I am not aware that there is.

Mr. CONABLE. I am simply repeating what people have said to me from my own college.

Dr. HAWORTH. I wouldn't know unless it is because we are able to fund a smaller fraction of proposals than NIH is.

Mr. DADDARIO. Dr. Haworth is happy to have the praise, anyway.

Dr. HAWORTH. At the same time, it is clear that we must initiate or accelerate movements designed to assist in the solution of several problems that the project grant technique used alone either does not help with or intensifies. First: Lack of flexibility at, say, the departmental level; it is difficult to support general, or centralized facilities and services such as shops, general-use computers, and special libraries. Second: some decrease of freedom of action of college and university administrators in determining the overall institutional pattern of development and growth; this pattern may be unduly influenced by the nature of programs finding most ready acceptance in Washington.

The institutional base grant was designed to partially offset these disadvantages. We believe that the scale of such grants should be increased and, in order to remove inequities to institutions receiving their primary support from other agencies, that a total Federal base should be used for determining grant amounts.

Since we first talked about it on Wednesday, I might digress to remind you what the institutional base grant is. Once a year we give a grant to each institution that has received research or research participation support from us in the form of project grants. This so-called institutional base grant is calculated using a formula which is based on the total amount of the institution's project grants.

For example, in the institutional base grant, the first $10,000 of NSF project grants is matched 100 percent, the next roughly a million dollars is matched 10 percent, and then down to 3 percent, and so forth, to a celling of $150,000. So these range from a few thousand dollars to $150,000, most of the money falling in the range of grants of a few tens of thousands of dollars.

The universities and colleges prize these funds very much, because they are able to fill in gaps, to do things that they couldn't do under the project system. This is partly because the project grants just don't cover some of these other needs, partly because to get a needed item for common use, machine tool or something of that sort, they would have to get several professors to pitch in from their own research projects and this is pretty hard to do. So these institutional

base grants have been, dollar for dollar, the schools all say, the most useful funds they have received because they are flexible. The grants are based on the level of our own research grants. No other agency has quite the same kind of program, although NIH has a similar one, especially in the professional schools. This gives rise to an inequity. For example, suppose that we supported a nuclear research group at university X using a Vander Graaff generator, and the AEC supported a nuclear research group using a similar machine at university Y. Then the university X would get an institutional base grant because their funds came from us, and university Y wouldn't because their funds came from AEC.

So we think we should make a transition, which will take some doing administratively, to basing our institutional grants on the totality of Federal funds at an institution rather than just on our own funds, in order that the happenstance of whether a university receives support from NSF rather than say, AEC, won't determine whether they get base grant funds or not. We would have to reconstruct the formula, of course, but that we can do.

We are also likely to continue to move toward more comprehensive research project grants that provide funds for coherent groups of related activities. In addition to the additional flexibility they allow, such larger grants have the important incidental advantage of reducing the administrative load on both the university and the Foundation.

A third problem is the concentration of research funds in a relatively small number of institutions. This is an undeniable fact. But it is equally true that this concentration of support results from the fact that those most capable of outstanding contributions to science and technology naturally gravitate to institutions which, over several decades, slowly accumulated notable faculties and excellent facilities. Federal support did not create this situation; indeed, to some extent it has already led to the accelerated building up of strong centers where there was only incipient strength a few years ago.

This leads me to a second question: How can we most effectively help build increased strength in institutions of higher education throughout all regions of the country?

In considering this matter we should bear in mind two related goals: First, we should try to assure continuous growth in the scientific capabilities of the country, which clearly means we must continue to improve the capabilities of our universities and colleges and, in particular, to increase the number of first-class institutions; second, in doing this we should try to make sure that all regions of the country come to have strong academic institutions.

We at the Foundation have given a great deal of thought to the problems posed by these two goals. We have recently identified four courses of action which should be followed in the effort to optimize academic science and science education throughout the country. These are not separate choices but part of a single, overall design; in part they represent a reaffirmation of longstanding views and policies, but they also offer special guidelines for the near-term future:

1. Outstanding quality should be maintained and even enhanced in those graduate institutions where it now exists. Excellence has no upper limit. Its existence invites challenge and competition as well as emulation, and it is not a self-perpetuating attribute, as the

history of some American universities demonstrates. As I pointed out Wednesday, such institutions are important national assets, because they are the leading sources of our scientific progress and their graduates are vital factors in energizing the entire national scientific structure, including the university and college community as a whole.

Our present programs are well adapted to serve their needs. The outstanding institutions—and the members of their faculties—can and do compete successfully for our project support and for facilities funds; they thereby qualify for—and thus receive—institutional base grants. They will continue to do so as long as we maintain programs that require competition on the basis of quality—as we must.

2. Increasing assistance should be granted to those graduate institutions which already possess recognized, though not necessarily outstanding research and educational competence, together with clear potentialities for effecting significant qualitative improvements. In recent decades a number of institutions have registered fairly rapid gains in quality—overall as well as in particular departments or fields. The number of such institutions with potential for development beyond mere competence, or with departmental "islands of strength" worth augmenting, is greater than is generally realized. Special efforts with proper timing are required if these promising situations are to be capitalized with a view toward enhancing the Nation's total capabilities for science and technology. The Foundation's science development program was established with these needs in mind. We intend to continue to exploit it in its present form. In addition, we are seeking to find ways to assist in building up and broadening "pockets of strength" in educational institutions whose present overall capabilities are not great enough for them to compete successfully for major science development grants.

3. Research funds should be made available to promising younger members of science and engineering faculties who have not yet achieved reputations and whose chances of securing Federal research support are understandably small, given the accepted and desirable criteria of proven merit and high quality. A young scientist located in a leading institution has opportunities to engage in meaningful research and win recognition through association with distinguished senior scientists who do enjoy support. Such opportunities are considerably less for young unknowns located at institutions which receive little Federal support for research or education. This group constitutes a research potential which the country should not ignore. Moreover, the roles of research and education are so interrelated that modest investments of research funds in these men will, at the same time, yield returns in better educational opportunities for the student bodies in such institutions. The Foundation is already experimenting with methods of assisting in this problem.

4. Assistance of appropriate kinds should be made available to help lift the general quality of undergraduate science education. Quantitative expansion of academic institutions to provide places for the stream of college-bound youth is not alone sufficient to enhance the capabilities of science. Also necessary is the provision of educational opportunities of sufficient quality to evoke and nurture the ability and talent contained in a burgeoning college population.

Failure in this regard would be at substantial cost to the Nation's future capabilities for science and technology. Additional assistance therefore should be given colleges, and the undergraduate components of the universities, for the development of improved curricula and teacher training, and for needed facilities, such as laboratories, equipment, and science libraries.

It is worth noting that at the suggestion of the Foundation these four courses of action have been adopted in principle by the Federal Council for Science and Technology as guidelines for the future: The first three for all the science supporting agencies—insofar as they are consistent with their respective missions and authorities—and the fourth for the Foundation.

Not only are these four courses of action directed at different needs of the academic community, but they also require different criteria for implementing them. In particular, it is essential that we continue to have both programs which stress present quality or merit as the primary criterion and programs that are pointed at the development of yet unrealized potential. We must be careful not to mix the two for it is essential in selecting proposals for support to use criteria that are appropriate to the objective sought—and these criteria differ from one objective to another. On the other hand thought should be given to sometimes combining different types of programs to achieve overall objectives, such as institutional strengthening. For example, in appropriate cases research grants and funds for facilities might be combined to support a particularly promising group.

In a different dimension, our assistance should be direct and with a minimum of redtape. We must avoid burdening good intentions and good work with a heavy bureaucratic load. The relations between the Federal Government and the Nation's universities and colleges must remain as flexible and simple as we can keep them. There has developed between the Government and the universities and colleges an intricate interdependence. This relation is delicate. It thrives when the requests the Government makes of educational institutions are consistent with their inherent goals. Everyone benefits by the simple act of strengthening those institutions. Everyone suffers when the Government imposes restraints, requirements, and restrictions which limit the academic or intellectual flexibility of the institutions. I am concerned that increasing Federal support has carried with it a tendency toward increased restraint. Simple examples are the increasing paper load in accounting for Federal grants-in-aid and the special conditions accompanying such grants. Because we, at the Foundation, have a special responsibility for the health of academic science, this concern weighs heavily upon us. It is my hope that the Foundation will develop simpler and less contraining techniques for the support of university and college programs; that is, techniques which return as fully as possible to the original spirit of the grant-in-aid.

Although these last few remarks were directed primarily toward programs in support of academic research, they are also applicable in large measure to our activities in support of science education. Let me now speak more specifically of our aspirations relative to this segment of our operational responsibility.

We must increase and strengthen our efforts to upgrade the quality of science education at all levels and in all fields. As time moves on,

we will be working even more closely with the universities and colleges in this endeavor. We have abundant evidence that this mode of operation is sound and effective.

In earlier comments I have dealt directly or indirectly with many of our hopes with respect to graduate and undergraduate education in the sciences. NSF will continue to deal with the qualitative and innovative side of such education. We will continue, possibly on a somewhat broader scale, to emphasize the value of research participation as an important auxiliary educational device at various educational levels. We hope to use our institutional support and facilities support activities more explicitly as elements in our approach to science education. And we will wish, of course, to continue and strengthen our fellowship and traineeship activities which have shown themselves so valuable.

As you know, we have been able to make a real impact on improving the subject matter education of teachers of science who are already teaching. We are now searching for ways of making sure that later generations of such teachers are well-prepared when they begin their careers. Our commitment to the achievement of this goal is greater than our understanding good ways of reaching it, but experiments already initiated may help us accomplish some of our hopes within the next few years.

We have, by virtue of our excellent rapport with the scientific community, succeeded in substantially increasing the number of scientists of competence engaged in activities for the improvement of science education at the precollege level. This has proven to be a most effective means of creating new interest in the qualitative improvement of courses of study, in teacher preparatory programs, and in the development of special opportunities for highly able and strongly motivated young men and women. Elementary and secondary school teachers, moreover, have been revitalized by the knowledge that there are indeed university and college faculty members who are interested in the subject matter of science at the precollege levels. Continued emphasis along these lines is called for, both to assure further qualitative improvements in science and mathematics instruction in our schools, and to insure effective use of the abundant and unique resources available for such purposes in our institutions of higher education.

Although our relations with the Office of Education are now quite close, they will become even closer. We will also maintain and strengthen our ties with all the other groups, private and public, that support programs in science education.

More generally, as time moves on, I see NSF assuming a more active role of leadership. Its traditional role has been an essentially receptive one—one which leads us to react to and support, to the extent we can, meritorious ideas of active scientists. Such a role may be described as one of enlightened opportunism. Thus we stand ready to receive and support good ideas, but only in a limited number of cases do we initiate activities.

In certain areas, our role must be a more active one. We must be more active in the promotion of, as distinguished from the support of, basic research. We must intensify our leadership role in our assigned responsibilities in the fields of weather modification and science information. There are whole classes of other problems in the national

interest which can benefit from concerted and directed initiative and leadership by NSF in fulfilling its responsibilities. Here I am thinking of problems in the engineering and social sciences as well as the biological and physical sciences—and, especially, of problems that can be dealt with only by teams of research workers drawn from two or more fields.

Mr. VIVIAN. Do you have a list of those areas in which you feel we should take a more active role in promotion rather than support?

Dr. HAWORTH. I think we should concern ourselves a good deal more than we have with some of the scientific and engineering—and I include the social sciences here—problems that underlie some of the social problems such as transportation, urbanization, and many things of that sort. These are not areas where proposals are stimulated simply by a receptive attitude, for two reasons. First, most scientists and engineers in the universities have not been very actively involved in these areas, and, secondly, these problems are not the kind that one individual can really attack very well. So the individual method of approach which has primarily characterized our research programs is not really effective for this broader kind of problem. What I am trying to say is that we have to think how we can encourage concerted attacks by people in more than one discipline or more than one institution on some of these broader problems. I have to confess it is still fairly vague in my mind, but something needs to be done about these things.

Mr. VIVIAN. I have the same interest and concern, but unfortunately it is also vague in my mind. I was hoping it was more solidly established.

Dr. HAWORTH. Some of the staff I am sure could talk more specifically than I if you would like to take the time.

Mr. DADDARIO. Not right now, Doctor.

Dr. HAWORTH. I have said this earlier, but I think it is worth repeating here and making it more explicit. The Foundation, over the years, has developed a number of programs to serve a variety of purposes. Some of these are further along than others. We are now at the stage where we can begin to round out our activities, to strengthen some programs, and to exploit others even more fully. The years before have been years of growth and program experimentation. We are now consolidating our gains. The years to come will be years of increasing fulfillment. But we must not stop the evolutionary process—for science is indeed an endless frontier and we must adapt ourselves to its ever-changing pattern.

In such endeavors the Foundation should take full advantage of the wide latitude accorded it by the Congress in the National Science Foundation Act. We have found this statute to be a remarkable and flexible legislative mandate, one which has made possible the timely introduction of new and novel mechanisms for coping with a variety of problems, both in research and in science education. As we survey the past policies and procedures of the Foundation, however, we recognize several areas in which there exists authorization over and above that which we have fully utilized heretofore. I believe that we can use these additional elements of our authority in ways which are beneficial to the Nation.

I have in mind much the same sort of thing as I had in answer to Mr. Vivian's question.

In closing, Mr. Chairman, I should like to pay sincere tribute. I believe it can be fairly said that the National Science Foundation has been successful; that it has come to be a vital force in the advance of science in this country; that its future augurs well. Its success results from many factors. It was conceived by brilliant men; it was established and has been supported by an enlightened Congress; it has been encouraged and inspired by four successive Presidents; it has been ably led by the National Science Board, Dr. Waterman and others. All this is widely recognized. What has not been so apparent to the world at large is the vital contribution of the members of its able, dedicated, and self-effacing staff. Without their effective efforts, all the wisdom, all the leadership could have led to naught. It is a privilege and a pleasure to be associated with them.

Thank you, Mr. Chairman.

Mr. DADDARIO. Dr. Haworth, I want to thank you for your 3 days of testimony. It has been extremely helpful to the committee. Your closing statement includes a great deal that we should all think about very carefully.

If there is no objection, we have some questions that we will send to you to be answered for the record, and we would like to have this done prior to the time you return at the close of the hearings. All of the members will have an opportunity, if they have any specific questions they would like to have answered, to submit them in writing.[1]

I would also like to thank your staff for being here and for helping to prepare this presentation. It has been a very helpful contribution, and a good foundation for the hearings which will continue through the month of July and through the first week of August.

We will be in touch with you, of course, from time to time, Dr. Haworth, as questions arise which we think we ought to talk to you about.

Thank you.

This committee will adjourn until next Tuesday morning at 10 o'clock at the same place.

(Whereupon, at 12:05 p.m., the hearing was adjourned until Tuesday, June 29, 1965, at 10 a.m.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, JUNE 29, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order. Our witness this morning is Dr. Donald F. Hornig, who is the Director of the Office of Science and Technology.

Dr. Hornig, we are pleased to have you here this morning.

STATEMENT OF DR. DONALD F. HORNIG, DIRECTOR, OFFICE OF SCIENCE AND TECHNOLOGY

Dr. HORNIG. Mr. Chairman and members of the subcommittee, it is a pleasure to be here. I am very happy to have the opportunity to appear before the subcommittee in connection with its comprehensive review of the National Science Foundation.

As indicated in your invitation to appear, Mr. Chairman, I will direct my remarks largely to the relationships between the Office of Science and Technology and the National Science Foundation, with some remarks on the Foundation's overall program.

The subcommittee has just completed 3 days of hearings with the Director of the National Science Foundation. You also have a detailed background report on the National Science Foundation prepared by the Science Policy Research Division of the Library of Congress. On the basis of your hearings and the background information available to the subcommittee, I believe it is unnecessary for me to recite—so I will merely underscore—the brilliant record that has been achieved by the National Science Foundation in strengthening American science and science education. Its programs have measured up to and have come to symbolize the highest standards of excellence. Its policies and practices have been characterized by imagination and creativity in forging relations between the Government and our educational institutions that have been of unquestionable benefit to both.

In framing the Foundation's basic legislation in 1950, the Congress wisely foresaw the need for developing and encouraging the pursuit of a national policy for the promotion of basic research and education in the sciences, and so charged the National Science Foundation. It also directed the Foundation to support basic research and education in the sciences to strengthen the Nation's scientific research potential.

In both its policy role and in its mission to strengthen American science per se, the Foundation was given a unique charter among the Federal agencies. However, the Congress did not appreciate the difficulties inherent in giving the Foundation a broad policymaking role, nor were its modest budgets sufficient for it to strongly influence the overall rate of scientific progress.

The Foundation is a coequal member of the sizable family of Federal R. & D. agencies and a small brother at that, representing some 14 percent of the total Federal support of academic research in fiscal year 1965. Given the Foundation's coordinate position in the governmental hierarchy, it could not be expected that the Foundation would be vigorous in developing national science policies for there was no means for inducing other Government agencies to follow suit short of the extraordinary device of Presidential direction.

A similar problem confronted the Foundation in carrying out its 1950 statutory directive to evaluate the scientific programs undertaken by other agencies of the Government. The bulk of federally financed research is financed by agencies with applied missions—in defense, space, atomic energy, health, etc. The Foundation's budget for fiscal year 1965 accounted for only 4 percent of the total Federal obligations for research. The amount and character of research required by a given agency to carry out its statutory responsibilities must be judged in relation to the overall programs and goals of the agency as well as to the programs of all other agencies. The Science Foundation could not be expected to evaluate the merits of research programs in relation to the statutory missions of other agencies. A unilateral attempt to do so would have inevitably impaired the external relationships of the Foundation and imperiled its own programs.

I have mentioned the difficulties inherent in giving the Foundation a broad policymaking and evaluating role. At the same time, I would like to emphasize the positive and highly constructive influence that has been exerted on the total Federal science effort through the Foundation's own policies and sponsored research at academic institutions, well in excess of its proportion of the Federal research budget.

The establishment of the National Science Foundation was one of a series of steps in the long history of evolution of science organization in the Federal Government. The evolution since World War II was accelerated both in terms of the number of agencies having major R. & D. activities and in the Federal investment in research and development. The next significant step in the evolving science structure took a different turn. In the mid-1950's the rapidly expanding research and development activities of the many Federal agencies and the growing potential of science and technology to contribute to the Government's programs and policies gave rise to increasing concern over the lack of central consideration of the many ways in which science and technology interact within the governmental structure. It was finally recognized that a major organizational innovation was required, and that the functions of central coordination and policy formulation for research and development could be carried out only at the highest level of Government—in the Office of the President. It was further recognized that Presidential leadership for this purpose required special staff support.

Immediately following the Soviet sputnik in the fall or 1957, the first special assistant to the President for science and technology was appointed to provide full-time staff to the President in dealing with matters pertaining to science and technology. At the same time, the President's Science Advisory Committee was reconstituted as a White House committee to make directly available to the President the considered views of 17 eminently qualified scientists and engineers from outside of Government; and through that committee and its panels, to make available to the President the views of experts from anywhere in the United States on special topics as they arise.

Mr. DADDARIO. Dr. Hornig, could we have for the record the present membership of the President's Science Advisory Committee?

Dr. HORNIG. Certainly.

(The information requested is as follows:)

PRESIDENT'S SCIENCE ADVISORY COMMITTEE—MEMBERS AND CONSULTANTS

Chairman: Dr. Donald F. Hornig, special assistant to the President for science and technology, the White House, Washington, D.C.

Vice Chairman: Dr. Herbert F. York, Jr., professor of physics, University of California at San Diego, La Jolla, Calif.

MEMBERS

Dr. Lewis M. Branscomb, Chairman, Joint Institute for Laboratory Astrophysics, Boulder, Colo.

Dr. Melvin Calvin, professor of chemistry, University of California, Berkeley, Calif.

Dr. Richard L. Garwin, IBM Watson Laboratory, Columbia University, New York, N.Y.

Dr. Marvin L. Goldberger, professor of physics Palmer Physical Laboratory, Princeton University, Princeton, N.J.

Dr. Philip Handler, chairman, Department of Biochemistry, Duke University Medical Center, Durham, N.C.

Dr. Franklin A. Long, vice president for research and advanced studies, Cornell University, Ithaca, N.Y.

Dr. Gordon J. F. MacDonald, Institute of Geophysics and Planetary Physics, University of California, Los Angeles, Calif.

Dr. William D. McElroy, chairman, Department of Biology, the Johns Hopkins University, Baltimore, Md.

Dr. George Pake, provost, Washington University, St. Louis, Mo.

Dr. John R. Pierce, executive director, Research Communications Principles and Communications System Division, Bell Telephone Laboratories, Murray Hill, N.J.

Dr. Kenneth Pitzer, president, Rice University, Houston, Tex.

Dr. Edward M. Purcell, professor of physics, Harvard University, Cambridge, Mass.

Dr. Frederick Seitz, president, National Academy of Sciences, Washington, D.C.

CONSULTANTS-AT-LARGE

Dr. Detlev W. Bronk, president, the Rockefeller Institute, New York, N.Y.

Dr. Harvey Brooks, dean, Division of Engineering and Applied Physics, Harvard University, Cambridge, Mass.

Dr. James B. Fisk, president, Bell Telephone Laboratories, Murray Hill, N.J.

Dr. James R. Killian, Jr., Chairman of the Corporation, Massachusetts Institute of Technology, Cambridge, Mass.

Dr. George B. Kistiakowsky, professor of chemistry, Harvard University, Cambridge, Mass.

Dr. Edwin H. Land, president, Polaroid Corp., Cambridge, Mass.

Dr. Colin M. MacLeod, Deputy Director, Office of Science and Technology, Washington, D.C.

Dr. Emanuel R. Piore, vice president and chief scientist, International Business Machines Corp., Armonk, N.Y.
Dr. Isidor I. Rabi, professor of physics, Columbia University, New York, N.Y.
Dr. Jerome B. Wiesner, dean of science, Massachusetts Institute of Technology, Cambridge, Mass.
Executive Officer: David Beckler, Office of Science and Technology, Washington, D.C.

One of the first studies undertaken by the President's Science Advisory Committee was an examination of measures required to strengthen American science, with special emphasis on the role of the Government. The Committee's report recommended the creation of the Federal Council for Science and Technology having as a principal function the provision of more effective planning and administration for Federal scientific and technological programs affecting more than one Federal agency. Sitting on the Federal Council for Science and Technology are policy-level officials from each of the major R & D agencies. This body continues today to be an indispensable forum for consideration of interagency problems and for focusing multiple-agency viewpoints in the development of common policies for the administration of agency research and development programs. The special assistant to the President has chaired both the Federal Council and the President's Science Advisory Committee from their inception, providing a vital coupling between these Committees and the concerns, needs, and actions of the President.

The concept and operation of the Office of the Special Assistant to the President for Science and Technology proved so useful to the President, to the other offices of the Executive Office of the President, and to the agencies themselves that the Office of Science and Technology was established in the Executive Office of the President by Reorganization Plan No. 2 submitted to the Congress by President Kennedy in 1962.

Its main purpose was to provide the President with permanent staff resources to assist him in developing policies and evaluating programs with the general objective of assuring that science and technology are used most effectively in the national interests. It was also aimed at providing more effective communication with the Congress on Government-wide policies and programs in science and technology. The Director of the Office of Science and Technology continues to serve in the role of special assistant to the President. The small staff of the Office provides support for the activities of the Science Advisory Committee, the Federal Council, and their numerous working groups and panels.

Mr. DADDARIO. Dr. Hornig, could you give us some examples of the way in which this is worked out? I am referring to your statement:

> It was also aimed at providing more effective communication with the Congress * * *.

In what ways has this proven to be effective?

Dr. HORNIG. Of course, my appearance here this morning is one example of such communication. I haven't kept an exact count, but I think I have testified before various committees roughly a dozen times this spring. In addition, we have published and sent to the Congress reports on the national program on oceanography, on water resources, and on atmospheric sciences. These are examples.

Mr. DADDARIO. Up until 1962, OST published annual reports of the work of Federal Council. Was there any particular reason this was discontinued?

Dr. HORNIG. I am not quite sure I know to what you refer.

Mr. DADDARIO. Annual reports of the activities of the Federal Council for Science and Technology were published up to 1962. I have seen some of these and have found them quite helpful. I just wonder why they have been discontinued.

Dr. HORNIG. I do not know how to answer that question except to say we are preparing one now for 1963 and 1964 because we thought one ought to be available. We will issue it shortly.

Mr. BROWN. Mr. Chairman.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Could I inquire further into the method of operation of the Federal Council? Does this have regular meetings? Does it engage in any activities other than talk amongst itself? Not that that isn't an important activity, but I am trying to visualize just how it functions.

Dr. HORNIG. The Federal Council does meet regularly; yes. It meets every month. It also accomplishes most of its work through a series of panels in those areas in which many agencies are engaged. For instance, the Interagency Committee on Oceanography is a member of the Federal Council; so is the Interagency Committee on Atmospheric Sciences; also, there is a Committee on Scientific and Technical Information. In these fields in which many agencies are engaged, the committees to the Council do much more than talk. They actually attempt to coordinate the programs, and they assemble for the Council information on both the content and the budgets of the total programs.

In oceanography the Interagency Committee has helped with such problems as ship scheduling to be sure that if agency A is sailing a ship for its purposes that this is known to agency B so it could send people along if it is interested in doing research in the same areas of the oceans, for example.

In the case of the Committee on Scientific and Technical Information it has been engaged in a very intensive interagency study of a national approach to the dissemination and free flow of scientific information and the utilization of the most modern technology for the purpose. This has been a planning function that it is engaged in.

The Council, itself, of course, was set up by Executive order, and its original role was to provide advice and assistance to the President. It in fact has gone beyond that role because in the course of talking, as you say, and exchanging information on agency practices, it found that although it is not in itself an action or direction group, through consensus it could achieve common actions by the agencies simply by comparing notes and deciding in effect that there was no reason to do things differently.

Mr. BROWN. This is the sort of thing I was interested in, whether they are seeking to solve some of these problems that cut across a number of areas. The one that you mentioned—the dissemination of scientific information—this is a problem which is of great relevance to the scientific community. Many agencies have different systems for collecting and disseminating this information, and it would be desirable if a certain uniformity could be achieved.

Dr. HORNIG. I liken what the Council is doing in this area through the Committee on Scientific and Technical Information to the role of the Bell System many years ago of tying together many of the telephone companies throughout the United States in a planning and staff way so that it is possible to dial San Francisco going through seven telephone companies without you as the consumer knowing that seven existed. I think we would like to be in the same position with respect to information. We have the local information systems—those of Department of Defense, NASA, and AEC for example—but when you look for information in the future you would not as a user have to concern yourself with where it happens to reside. I hope we can tie these together so, like dialing, you can find your way to whatever you want to know wherever it resides.

Mr. MILLER. Mr. Chairman, I think the problem is one which is not at all simple, and one in which the executive department bears only half of the burden; the other part must be accepted by Congress.

We have grown up with these things. Science is spread throughout the gamut of committees of Congress. When you try to tie areas of science together, the interdisciplinary fields, you find one committee having jurisdiction over one facet of the problem, and another committee having jurisdiction over another. It is something that the Congress has to work out, not the executive department.

I think Dr. Hornig cited the case of oceanography. You will find oceanography having its roots in about seven different committees in the House. They are all jealous of their powers and authority, and no committee wants to give up any of its power. The result is we have had numerous bills trying to solve this problem. Perhaps there is not a more important facet of study that we have to deal with than oceanography; yet, you cannot look to any one place to get it, and the overlapping is great. So, we try to solve it by setting up an interdisciplinary or an interagency committee, but these have never worked out too well, not only in this field but in any field. If it had not been that the President and Mr. McCormack were interested in space in the early days and set up this committee that evolved NASA, space would find itself in the same position as oceangraphy, with no one to plead its cause.

I believe that we in Congress have a responsibility, and we have to accept it. It is not going to be easy anymore than it is with our jurisdiction over NASA. We find few jurisdictional disputes. We have been able to resolve them all right, and we hope we continue in the future to do so. I just want Dr. Hornig to know that at least some of us appreciate the position he is in, and I know he appreciates the position that we are in. It is a challenge to all of us in the field of science to try to bring some order out of chaos.

Dr. HORNIG. If I may interrupt my testimony, I would like to comment on two aspects of the very wise remarks that the chairman has made. It presents difficulties for both the Congress and for the executive; this division has its roots in part in the nature of science. You might use oceanography as an example. One can, on the one hand, talk about a national program in oceanography. On the other, it is also perfectly true that with respect to those elements of oceanography that are concerned, for instance, with the operations of the Navy, whether or not there were a national program in oceanography, the

magnitude of our effort would be determined by our national defense needs. As a matter of fact, even in the presence of a national program, this is one segment of the activities whose scale is decided not by what one thinks about oceanography, but what the Navy needs from oceanography. And similarly the effort in fisheries resources, for example, is tied in part to what we expect from the ocean and fishes. Of course, in pursuing these separate goals people sometimes do the same thing. That is why we try to assemble a program. I don't think there ever will be a perfect administrative solution either in the executive or in the division of responsibilities among congressional committees.

Mr. MILLER. Democracy, Doctor, is not a dead thing. You never fully accomplish it. It is as alive as the people who form the government, and so long as this is true, there are going to be changes taking place. We are always going to be confronted, I think, with the problem we have today.

Dr. HORNIG. I think that is very true. In fact the vitality and freshness of the viewpoint we have, by having people look at problems from several different points of view, probably far outweigh the loss of administrative neatness that we may have.

Mr. DADDARIO. Yet, Dr. Hornig, the changes which have taken place in the National Science Foundation since it was founded, and the transfer of some of its functions to your office came about because we wanted to have different points of view, but not too many. You have to keep some order to it, and this is what we are really talking about.

Dr. HORNIG. I think that is correct. To say that one wants diversity does not mean that one wants chaos. I think that is true in both the Congress and the executive. I will touch a little bit more on that in my prepared testimony, if I may continue.

In recognition that the development of science policies affecting several agencies and evaluating agency programs can only be performed at a higher level. Reorganization Plan No. 2 was based on a transfer of two functions from the National Science Foundation to the Office of Science and Technology. First, it split the function of developing and encouraging the pursuit of a national policy for the promotion of basic research and education in the sciences by transferring to the Office of Science and Technology as much of that function as would enable the Director of the Office to advise and assist the President in achieving coordinated Federal policies for these purposes. The National Science Foundation retained the balance of the authority, including explicit responsibility for developing policies to govern NSF programs for the promotion of basic research and science education.

The reorganization plan also transferred to the OST the 1950 function of the National Science Foundation to evaluate scientific research programs undertaken by other agencies of the Federal Government. It left in the Foundation statutory responsibility for correlating its scientific research programs with those undertaken by individuals and by public and private research groups.

Mr. DADDARIO. Could you give us some examples of the way in which OST has evaluated scientific research programs after this function was transferred to it from the National Science Foundation?

Dr. HORNIG. I suppose the most explicit recent example I can cite is the report of the Wooldridge Committee. The exact title is "Bio-

medical Science and Its Administration: A Study of the National Institutes of Health." This is a study in depth of the quality of the NIH programs and of their administration. This report was published this last spring, as you may remember.

Mr. DADDARIO. To whom do you make your recommendations? How does it come out with a report and translate that into action?

Dr. HORNIG. Of course, the whole mechanism is set up essentially to advise and assist the President; so, putting results into effect consists of a process of in many cases talking to individuals, and sometimes it translates itself into legislative programs which the administration submits to the Congress.

Mr. DADDARIO. Do you see this as a mechanism through which OST can in fact sharpen the objectives and achieve better purposes so far as national goals and objectives are concerned? Does this appear to you to be a way in which we can make better choices and establish better science policy in the future?

Dr. HORNIG. What I would like to make clear in this goal is that OST is a very small organization so that we cannot and do not attempt to perform this evaluation function in detail by looking over the shoulders of agencies in the ordinary performance of their performance of their missions. OST has had to confine its efforts, and I think this is a good thing, to what we call major policies and programs. With respect to the question you asked——

Mr. DADDARIO. If you could just follow that up a moment, you have already stated that the National Science Foundation could not in fact look over the shoulders of other agencies. Since this function was transferred to your office and since you do have the opportunity to look over the shoulders of other agencies, are you somewhat restricted in doing so by choice or because of a limited number of staff personnel? If that is so, should that be changed; do you have any recommendations in that regard?

Dr. HORNIG. I think it must be said that we are still feeling our way as to what is best. We have a horror of becoming a new bureaucracy with little fingers in every part of the Government. I have not myself felt very sanguine about having a super-White House structure which would try to interfere in an operational way with the functions of the agencies.

I think our limitation, nevertheless, has been in the size of the staff. This year, for example, we have requested of the Congress an enlargement of the staff by four members. That isn't drastic, but that is about 25 percent, which I think in 1 year is about the right rate of going ahead. At least in the House, favorable action has not occurred.

I think it is true in the sense that the chairman mentioned that the committee method of looking at things is excellent for collecting information; it is not a good way to provide leadership for action. That rarely comes from interagency committees. For that purpose I think we do need a somewhat larger staff and organization than we have now. We are trying to look ahead in this goal-setting.

We are running this summer a big summer study under the chairmanship of Dr. Brooks, who is in the back of this room. By big I mean 15 men devoting 6 weeks of their time, but they are all topnotch people. This summer study is going to try to lay down some

rational guidelines for academic research and for its growth, and these questions of how you choose among field support and how you relate the efforts of the many agencies that are involved.

So, we are trying, I think, to the limits of our staff capacity and also our ability to really comprehend the problems, to set out more rational goals, policies, and guidelines for the total Federal program.

Mr. DADDARIO. Then, in a sense, Dr. Hornig, you intend to build up your staff capability. It would seem to me that you should do this, taking into consideration the support functions that you provide for the Science Advisory Committee, the Federal Council, and all the other working groups and panels. But once you say that and bring out the program you have with this group under the leadership of Dr. Harvey Brooks, in whom we do have great faith, you are in fact looking over the shoulders of these agencies. It is your intention to bring some order and direction from your office into the very functions of these agencies. What direction, then, does that bring you to, and what is the National Science Foundation's function in this process?

Dr. HORNIG. Of course, there is some interaction among the individual agencies. Our goal, if you like, is to act to some extent as 1 government and not 20 autonomous governments, so that when the policies of individual agencies interact with the policies of other agencies, then we should be involved.

Now, as to the National Science Foundation, it is, of course, the only agency which has as a fundamental responsibility the health of basic American science and of science education. I think, myself, that its role ought to expand relatively. As you know, the budget we submitted this year moved in precisely that direction. This may be an example of our activities.

We looked over the plans of all of the agencies for the support of academic research. We looked at the projected growth of student enrollments for the coming year and the probable increases in the costs of educating them and allowing them to carry on research and concluded that something like a 15-percent increase in the total national program in basic research in the universities was desirable for this year.

Then, the second decision was, because of the Science Foundation's particular responsibilities in this area, that this 15-percent growth should be concentrated, not exclusively, in the Science Foundation. The budget funds were requested for an increase of very nearly 50 percent in the Science Foundation portion of the budget for the support of basic research in universities. At the present time it doesn't look as if we will obtain that from the Congress. This has the effect that we are not going to be supporting university science students as well next year as this year because the growth in student population is one of the inexorable things that we are living with.

Mr. DADDARIO. You foresee, then, that in the event the Congress does not appropriate the funds in the amounts requested, that there will not be within the National Science Foundation the flexibility to transfer funds in order to achieve this particular purpose. This seems to me to be an important function, and perhaps more important than the allocation of its funds for other programs.

Dr. HORNIG. Its other programs are very important, too. Of course, in the action it was instructed not to cut its appropriation for the science development program or for its high school teacher programs at all. In fact, it was instructed to spend a little bit more on

the high school teaching program in the House action than it had budgeted. So, in its flexibility to reallocate funds it has in fact been constrained. Of course, it is left with some flexibility.

Mr. YEAGER. In connection with your statement that the OST function is to evaluate scientific research programs undertaken by agencies of the Federal Government, would it be a fair statement to say, in effect, that there is some evaluation here by recommendations that you make in connection with the annual budget process?

Dr. HORNIG. Yes, indeed.

Mr. YEAGER. Would this be as part of OST's function or the Federal Council's function, or both?

Dr. HORNIG. This is primarily an OST function, but the OST in this sense acts as a funnel for utilizing all of the sources of information and advice that are available to it. In this sense the Council, of course, is one of the principal information inputs.

Mr. DADDARIO. Please proceed, Doctor.

Dr. HORNIG. This logical realinement of functions has enabled the National Science Foundation to participate more effectively in the science policymaking process and to develop stronger programs of support than would have been the case were there no Office of Science and Technology. The Foundation continues to have full intellectual responsibility to examine, make policy recommendations, and take actions with regard to enhancing the health of American science which, as I previously indicated, is a unique responsibility of the Foundation.

The Office of Science and Technology provides a means to secure action on matters arising from the Foundation's activities that impinge on other agencies. It also permits the Foundation to take the lead, when requested by the Office of Science and Technology in organizing and carrying out interagency studies and evaluations. While the Office of Science and Technology looks to the Foundation for assistance in the broad areas of NSF responsibility for dealing with science as a whole, it has not interfered with the Foundation's internal operations and programs.

In consideration of these shifts in responsibility, I will discuss the relationships of the National Science Foundation to the science structure in the Executive Office of the President in two categories.

First, there are the special relationships between these two organizations that depend on the unique functions and capabilities of the Foundation:

1. The Science Foundation serves a central function for the Nation as well as for the Government in providing basic data on science resources and on the nature of Federal R. & D. expenditures, for example, through its Federal funds for science series and special analyses of Federal R. & D. expenditures. The data acquisition and analysis capabilities of Science Foundation are utilized by the Office of Science and Technology to provide a basis for the development of national science policies.

We see a need to supplement this excellent statistical series with more special analyses of problem areas in the support of science and science education. Such subjects as undergraduate science education, the use of postdoctoral students in research, geographical distribution of research support, and facilities for research would seem to offer

rich opportunities for analyses and assessments with policy and program implications. The conduct of such special area studies will in turn provide guidance for the gathering of statistics.

I will interject here the problem in all statistics gathering exercises is to make them coherent and to know what you are gathering statistics for, otherwise it is possible to expand them indefinitely and not to have them focus.

Mr. DADDARIO. In regard to the problem of keeping statistics up to date and their effectiveness if they are not up to date, the National Science Foundation put out a report in 1964 called "Industrial Research and Development Funds." In reference to it an article in Industrial Research Magazine said, and I quote:

> The rapid growth of research in industry makes the 1958 statistics appear ridiculous.

These were the 1958 statistics used in the NSF report of 1964.

Dr. HORNIG. One would like to have one's statistics current. One would also like to have statistics reliable. And these two objectives, not just in the Science Foundation, often conflict. One can get rough and ready figures ready, but detailed and solid figures often take a long time to check out. I wish there were slightly more current figures particularly on the industrial R. & D. side.

Mr. DADDARIO. Is there any reason why we could not have more reliable and more current statistics? You say you wish there were more up-to-date statistics on industrial R. & D. That being the case, if it would be helpful, why can't we have them, and how far back ought we to go?

Dr. HORNIG. Dr. Haworth could probably answer that better than I can, but I see no reason why we can't have more faster if we enlarge the effort and spend more money doing it. I mean more statistics collection, analyses and organization takes more people and more effort. There is always a question here, just as in the Bureau of Labor Statistics or anywhere else, how much you want to plague the world with questionnaires and data gathering. There is a question of balancing the value of the statistics gathered and the nuisance value of collecting them.

Mr. DADDARIO. If it is a plague, it ought to be a mordant one. It is important for this committee to take into consideration what recommendations and advice we get from you and other witnesses. Is this one place where in fact a greater effort ought to be made? Is it of such importance to the issuance of reports and the reliability which we can levy on those reports, that we ought to provide the National Science Foundation with the tools so that statistics can be as current and reliable as possible?

Dr. HORNIG. I think so, but I would add still that we conducted a considerable effort about a year ago through the Federal Council's long-range planning committee on trying to look ahead and to ask what information we needed to do a little forward planning. Now, it was quite clear the base is inadequate, and this would concur with what you have said. On the other hand, the hardest problem turned out to be to define clearly what statistics you really wanted, what statistics were really worth the effort, so the effort must not only be expanded, I think it should, but we are going to have to continue to

work and focus on what are the statistics that are really useful in an operational sense to the Government.

Mr. DADDARIO. New sampling techniques and this kind of thing?

Dr. HORNIG. Yes.

Mr. ROUSH. Dr. Hornig, in your opinion, is the National Science Foundation using the most modern, up-to-date equipment and techniques in this matter of gathering statistics?

Dr. HORNIG. I think the Science Foundation has done an excellent job. I think they have at times been a little slow, but as far as I can see they are doing an excellent job in collecting the statistics. Of course, they rely for many of the statistics on other organizations, both in the collection of internal Government statistics, where they rely on other agencies, and particularly when they go to the outside they rely on external data from industry, for example, so it isn't entirely within their control.

Mr. ROUSH. Has the Congress provided them with all the tools they need in this regard, or have they been denied certain tools?

Dr. HORNIG. I think this is a question Dr. Haworth would have to answer.

Mr. DADDARIO. Would you continue, please?

Dr. HORNIG. 2. The Science Foundation can serve either as an executive agent or a delegated agent of the Office of Science and Technology in taking the lead in connection with certain programs of broad importance. For example, the Science Foundation, at the request of the Office of Science and Technology, developed an interagency assessment of and reaction to the report of the National Academy of Sciences on needs in ground-based astronomy.

In the scientific and technical information area, the OST looks to the Science Foundation to provide leadership in effecting cooperation and coordination among non-Federal scientific and technical information services and organizations, and in developing adequate relationships between Federal and non-Federal scientific information activities.

The Science Foundation has provided support for a series of surveys by the National Academy of Sciences of research opportunities and needs in various fields of science, including chemistry, physics, and the use of computers in universities. This source of recommendations to the Federal Government has proved invaluable in the planning of Federal science programs.

3. The Foundation is a particularly valuable source of advice to the Office of Science and Technology on science policies that merit consideration for Government-wide application. Because of its broad charter, the Foundation, in planning its own programs, must necessarily take into account the science and science education activities of other governmental as well as private agencies.

The National Science Board has in recent times intensified its activities in developing policies for the Science Foundation, and we in the Executive Office regard this as a significant development that should lead to better understanding and to policies for guiding Federal science activities broadly. The actual formulation of Government-wide policies is normally undertaken through the Federal Council for Science and Technology or by the Office of Science and Technology in direct consultation with interested agencies.

4. The Science Foundation, with the support of the Office of Science and Technology, has increasingly taken into consideration the extent and character of the programs of other Federal agencies in the support of research at academic institutions. So that academic institutions supported by several agencies can take more initiative in their own science development and correct weaknesses that may arise or are not dealt with through agency research support, the Foundation expects to broaden the base of its institutional grant program to take account of the total Federal support of research at a given academic institution.

What I am referring to here is in the past the National Science Foundation institutional grants have used as their base the National Science Foundation expenditures at a given institution. They expect, beginning next year, to use as the base the total Federal Government expenditure.

As the result of an OST-Bureau of the Budget assessment of the needs and plans of all Federal agencies for the support of academic research in fiscal year 1966, it was found that a very substantial increase in the academic research support by the National Science Foundation would be required as the graduate student body and science faculties grow.

Mr. DADDARIO. Dr. Hornig, why would that be an OST-Bureau of the Budget assessment rather than a report submitted to your office or the Office of the President by NSF itself?

Dr. HORNIG. I think the problem last year was largely a practical one—the ability of any one agency's participating intimately in the planning of the other agencies and in order to be aware of their budgetary situation. Formal reporting procedures during the budgetmaking process get pretty slow. Although the budget is put together beginning in the spring, intensive activity really occurs from September to December.

Mr. DADDARIO. Yes, but should it begin with the Bureau of the Budget or with NSF? Should NSF make its own evaluation as to what it ought to do insofar as this particular subject is concerned? Then perhaps have your office and the Bureau of the Budget come to some decisions among themselves about it, especially in view of the fact that the NSF does have this responsibility? The Reorganization Act has transferred some of NSF's jurisdiction to you, but not this, as I see it.

Dr. HORNIG. Well, the problem looks like this. The NSF support is about 14 percent of the academic research budget; it is only 4 percent of the total research budget. It is exceeded in its contribution to universities by both the National Institutes of Health and the Department of Defense. Both the AEC and NASA support about half as much as NSF. So the question of what is proper and wise for NSF to support is very intimately tied to the plans of the Department of Defense and the National Institutes of Health. The National Science Foundation should quite properly provide advice as to what is required in the way of basic research for the country. But in translating this into budgetary terms, it is very sensitive to what the other agencies do, and it cannot know that until after preliminary budget decisions have been made. The problem to which we have begun to

make a successful approach is to try to know toward the end of the budget review how the totality is going to look for the next year.

Mr. DADDARIO. Then, I would assume that OST and the Bureau of the Budget could decide how much ought to be performed in each of the agencies. The direction, then, would come from OST and the Bureau of the Budget, and it would not necessarily have anything to do with the objectives of each of those agencies. There may be violent disagreement which the Congress might never know anything about. I don't put that out in a critical way but just as a supposition.

Dr. HORNIG. This is really the problem to which the chairman alluded earlier, both in connection with the Congress and the Executive. All of these programs have to be looked at from several points of view, both as part of a continued science program and also in relation to the objectives of the agencies individually. All but the NSF have other objectives than simply the health of academic research.

Mr. DADDARIO. Of course, we recognize that these problems exist. Yet, as we work closer and closer together, the situation should get better rather than worse. It seems to me that the National Science Foundation should make its needs and plans known so that there can be some review of these, and appropriate recommendations made about them in consideration of the problems involved in allocating funds to all of the agencies. This would appear better to me, rather than to have it appear, as it does here, that the OST and the Bureau of the Budget just figure out what is available, and carve it up and put it into slots, instead of making a determination of what is best for each agency.

Dr. HORNIG. Perhaps I should explain this a little bit further. This was not a carving up exercise. As we faced the budget last year, we began to worry as to what the effect would be on the NSF and on all of the other agencies, particularly if the research budget of the Department of Defense were held level, which, looking back in the previous year, seemed to be the intent of the Congress. In fact, the NSF participated and provided much of the staff work for the study I refer to, which was just the beginning at this sort of thing. I suppose it might have originated at an earlier time from NSF all by itself, but when one sees the necessity, one goes ahead, and that was, I think, the basic history. NSF participated very intimately in getting together the data for the assessment I mentioned, in the fall. But that is just really the first step. It would have been very hard, from within the NSF, however, to have arrived at the other major conclusion of the budgetary discussion last fall: that NSF's share in the Federal support of research ought to be increased somewhat. This year's budget would increase the NFS role from 14 percent to something like 19 percent. Now, one may call that carving it up, but it is actually a more fundamental approach. I don't believe NSF can exercise the role that was intended for it unless it is responsible for somewhat more than that 14 percent. I don't know what the optimum fraction is, but I think that NSF has, in fact, to be the source of a fairly considerable fraction of the basic research support if it is to really exercise its basic functions.

Mr. DADDARIO. I am sorry that I stopped you in the middle of the paragraph: I have been trying to wait until you finish. You were in the second sentence of that paragraph.

Dr. HORNIG. I had mentioned as a result of this study, which was participated in very intimately by the Foundation, that we had looked forward to the anticipated total needs of the Federal Government. The Foundation took the study into account and responded to this need in its fiscal year 1966 budget request. I hope that the Congress will recognize that the National Science Foundation must perform a "balance wheel" function in maintaining a steady and healthy overall growth in American science and science education, taking into consideration other sources of support.

To accomplish this task it will be necessary to increase the NSF's fraction of total Federal support in the universities substantially above the fraction in past years. If, as now seems likely, this increase in the National Science Foundation's fiscal year 1966 budget is not granted by the Congress and the academic research budgets of other agencies are cut, the 10 percent more graduate students in science, who will be there next year will not be as well supported as their predecessors.

A second type of relationship between the Science Foundation and the Office of Science and Technology characterizes the relationship between OST and all Federal R. & D. agencies:

1. The Office of Science and Technology and the President's Science Advisory Committee review and examine the programs of the National Science Foundation in the same way as they look at the programs of other agencies. Because of the smallness of the OST staff resources, this examination is highly selective and concentrates on items of major importance. The Office of Science and Technology does not attempt to systematically cover the detailed programs of the agencies. It is concerned mainly with the directions in which the programs are tending, the opportunities that may be neglected, and the major budgetary issues. It endeavors to assist and encourage the agencies themselves to strengthen their capabilities, quality, and resources so as to lessen the need for detailed involvement of the Executive Office agencies.

2. The Science Foundation participates as a full member of the Federal Council for Science and Technology in coming into agreement with other agencies on common policies for the administration of research and development, and in developing a consensus on the level and distribution of effort desirable for broad areas of research that cut across the programs of several agencies such as those in oceanography, high-energy physics, and atmospheric sciences.

The detailed work of the Federal Council is accomplished by means of a number of panels in substantive areas. Most of the panels are chaired by agency personnel. It is necessary to rely on the Science Foundation and other agencies to provide staff assistance to the panels and to undertake analyses in depth as will assist overall review and evaluation of the technical program area.

I have sketched in general terms various ways in which the Office of Science and Technology and its associated mechanisms interact with the National Science Foundation. Although this relationship has been productive, major problems lie ahead which will call for stepped-up efforts to develop new and improved approaches to the planning of the Government programs for the support of academic research and

for relating this research to the large science programs aimed at particular national objectives. This, in turn, calls for even closer cooperative efforts between the OST and the NSF. This summer the President's Science Advisory Committee is undertaking a 6-week study which we regard as a first step in the direction of developing guidelines for Federal support of academic research. The study will rely heavily on the staff resources on the Science Foundation and will inquire into such matters as the criteria for distribution of funds for research at the universities so as to reinforce the scientific excellence that exists in selected institutions, to increase the number of first-rate institutions, and to broaden the base of scientific research and education. There will be consideration of ways to broaden the geographic distribution of support to universities. The balance between project support and increased institutional responsibility for larger program elements will be examined. The role of postdoctoral students will be studied to determine whether policy guidelines for their support can be developed.

Mr. DADDARIO. What will result from this PSAC study, particularly with respect to its effect on the budget You have obviously put it together for some reason, and I wonder what your objectives are in that regard.

Dr. HORNIG. I think our objectives in the first instance are to understand the situation, to try to decide what our goals ought to be, and then, of course, if we can find a rationale for our continuing development, to translate that into budget and action items. But in the first instance, this study is to begin to try to understand and delineate what we are up to. I think this is characteristic of the Science Advisory Committee, in that it is not involved as deeply in the immediate operational aspect of the Government as in its attempt to provide a good intellectual framework for governmental policies. Its members are, of course, primarily from outside of the Government.

Mr. DADDARIO. On the previous page you talked about the work in oceanography, high-energy physics and the atmospheric sciences. These cut across the broad areas of research. How do you see NSF's function in this regard in the future? Do you envision an increasing role of this type?

Dr. HORNIG. Let me cite an analogy to a typical research laboratory. A problem that all advanced industries face is that there is applied and developmental work which is aimed at either the products they are producing or at finding new products. These are the mission-oriented parts. Most of the advanced industries also have found it important, however, to maintain some sort of a central research laboratory which is divorced from the short-term needs in order to lay a general base for the future.

The situation is somewhat analogous here, in that in areas like atmospheric science there is a very practical problem, and that is predicting the weather. We are all concerned with it, and this is the job of the Weather Bureau. Some research has to be done which is directly tied to the operations of the Weather Bureau and over a reasonably short term improving its operations. Work has to be done to assimilate the latest findings of basic research in the atmospheric sciences relating to, say, the total circulation of the earth's atmospheric, mechanisms of precipitation, and so forth, getting this into the

weather forecasting process. But above and beyond that, if all of the researching we do is tied to, in this case, weather forecasting, one would have no basis for longrun improvement, for example, for someday tackling and being successful with the problem of modifying the weather to suit our needs. So there is a separate problem of promoting the understanding of what makes the weather in the first place, and that is the central role of the National Science Foundation, whereas the prediction of the weather is the role of the Weather Bureau. There is never going to be a completely clean line between those two functions, but they are different.

Mr. DADDARIO. Then you do see an increasing role for NSF in this kind of operation?

Dr. HORNIG. I think the central role of the NSF was well stated by the Congress in the first place; I have given just this one example, but it is to insure the health of the underlying basic science and science education on which our whole structure of applied science and practical application depends in the long term.

Mr. DADDARIO. How far can NSF get into the practical application under the organic act?

Dr. HORNIG. Under the organic act, it is not completely crystal clear. It can't get very far, because the organic act directs it to provide for basic research. It also provides for engineering education, and there is, of course, a slight contradiction in terms, perhaps, in words like basic research in engineering, since engineering is concerned with the application of knowledge. So to that extent I suppose the organic act is a little bit ambiguous, but for the most part the organic act certainly restricts the NSF to basic research. I think there is a genuine problem here, when one worries about the transfer of basic research to applications in areas where we have no agency which is waiting as an avid consumer. I haven't thought this through completely, but it seems to me that one must examine whether the NSF perhaps shouldn't place a little more attention here, perhaps the legislation should be modified, but I want to think this through further, to enable it to devote a bit more attention to the information transfer problem, the transfer to applications.

Mr. YEAGER. Might it not be a good idea for the NSF to become a little more involved in applied science where issues of broad public interest are concerned, such as pollution or something of this nature? At least it might be made permissive.

Dr. HORNIG. It might. The reason I say I want to think about it, going back to my analogy of industrial establishments, the reason that most industries insulate their central research laboratory from their technical laboratories and their technical service laboratories is the danger that the demands of the day-to-day needs will overwhelm the needs for basic research, which are never urgent in the next month. We must consider if, by assigning too many practical tasks to NSF, one might not overwhelm the basic function that it serves so well.

Mr. DADDARIO. The other danger is that of being completely isolated so it will not bring about the transfer of the practical applications. The question is should the National Science Foundation be restricted to basic research, so isolated, so as to not have the capability to become involved in the fields of practical application? I know you have already touched on such areas as the atmospheric sciences. Is it beginning to move in that direction anyway?

Dr. HORNIG. I think this is a matter which deserves intensive study, and the Science Foundation, of course, is thinking about it and will make its recommendations. It is certainly something that we have been thinking about. Quite aside from the Science Foundation and all of science, I have been worried about the balance between basic research and applied research and the problem of bringing them together so there is an efficient flow of innovation into not only applied research but into industry and industrial practice.

Mr. DADDARIO. You raise some intriguing points in this regard, Dr. Hornig, and I am pleased that you have raised them.

Dr. HORNIG. Beyond the matter of Federal support of scientific research and education in academic institutions, there are major questions which we will need to probe regarding the evolving role of the Science Foundation in supporting science. There is the question of increasing NSF support of scientific activities that are directed at particular national goals without neglecting scientific opportunities as identified by talented scientists. There is also the question whether proportionately more attention should be given to programs and measures to promote the application of scientific knowledge when it does not fall within the purview of one or the other of the mission-oriented agencies. This would include measures for improving the national systems for the dissemination of scientific and technical information, and increased attention to education and academic research in engineering.

In summary, Mr. Chairman, the structure for national science policy formulation and management has evolved in recognition of the importance of maintaining the diverse pattern of support of research and development by the many agencies of the Federal Government since research and development cannot be uncoupled from the practical purposes which they serve. The National Science Foundation can play a most valuable role by helping to develop national science policies, by contributing its experience in carrying out its broad responsibilities for support of research and education in the sciences, and by making its professional and statistical resources available to the Office of Science and Technology.

I will be glad to answer any more questions.

Mr. DADDARIO. Dr. Hornig, have you thought out the ways in which increased attention to education and academic research in engineering ought to develop?

Dr. HORNIG. I will give you some views, but it is a question which is still very much under discussion within, for instance, the Science Advisory Committee. Engineering education has undergone a revolution since the last war, and largely in the direction of engineering sciences. One of the things that emerged during the war was the importance to engineers of having a sound theoretical and scientific foundation. There has been in our engineering education a reaction against the old cut-and-try kind of engineering. There is no question whatsoever in this respect that the quality of engineering education has improved very markedly in the last 20 years. Nevertheless, there are people now who inquire whether we haven't overshot the mark, whether engineering training, particularly at the advanced level, hasn't gotten a little bit removed in some cases from the basic objective of application, whether graduate research for the Ph. D. engineering

degree shouldn't take some other form than essentially the pure research of the physicist or the chemist or the mathematician. I don't have an explicit recommendation here. I think there genuinely is a problem in engineering education in both retaining this sound theoretical foundation which allows the engineer who is trained today to have a base for dealing with the problems of 10 or 20 years away, on the one hand, but also having an outlook which focuses on doing things rather than studying things. I think, in a nutshell, what some people are worring about is we may be moving too far in training a generation of engineers who study things rather than carry them out. However, I am sure that Mr. Vivian understands this problem very well.

Mr. VIVIAN. They seem to manage to carry out a large fraction of the national budget so far.

Dr. HORNIG. This I should say: In the conduct of our space program, our defense programs, and in the growth of our industries, our engineers have acquitted themselves very well, despite these observations.

Mr. DADDARIO. Do you have any questions, Mr. Roush?

Mr. ROUSH. I am not sure whether or not this has been answered, perhaps indirectly, but I have on my desk a report, a favorable report, from the Government Operations Committee concerning the proposal for a Commission on Science and Technology. How do you feel about the establishment of such a commission, Dr. Hornig?

Dr. HORNIG. My view a year ago had been that we ought to have more time to see how the relatively new mechanisms we had established were going. I think enough time has elapsed now so that I, myself, think this might be a good idea. I certainly wouldn't object to it.

Mr. ROUSH. I have no other question for the present.

Dr. HORNIG. May I amplify my previous remark simply to say that my answer was a general one, and I am not prepared offhand to comment on the specific terms of reference of the proposed commission.

Mr. DADDARIO. That is flexible enough.

Mr. MOSHER. Dr. Hornig, within the Government where does the prime responsibility lie today for the dissemination of scientific information, that is, a central point for making available information efficiently and readily? Does any one agency have this responsibility, or should any one agency have this responsibility?

Dr. HORNIG. There is no one point that is responsible for the dissemination of all information. I think it is doubtful whether one wants one point.

To look back at the classic problem of information dissemination in this country—this isn't a new one—one can look at the library system. We have a Library of Congress which contains samples of almost everything that is printed. On the other hand, no one would urge really that everyone who wants a book ought to get it from the Library of Congress. So, the important question is whether there exists a good mechanism by which anyone can get to the desired information.

At the present time, though, there exists no central planning responsibility for such a mechanism or system, which may be more important. To cite a few things, the Office of Technical Services in the Department of Commerce does have the responsibility for being a single point of access to all of the Government report literature, so

that information that is generated as a result of Federal R. & D., and which is not classified, can all be obtained from the outside through the Office of Technical Services. But beyond that the National Library of Medicine undertakes the principal role in the dissemination of medical information. The Atomic Energy Commission, the Department of Defense, and the Department of Agriculture all maintain information services which work within their specified areas. At the present time the Committee on Science and Technical Information of the Federal Council and Mr. Knox of my office, have taken a central role in trying to tie these together in a planning sense, but I think we must look forward to an agency outside of my office acting in the long term as a central agency for knitting together these separate information systems.

I think again this is something I would hate to provide a final answer to. One might set up a new agency but I am very worried about setting up science information specialists separate from the people who deal with science in substance. So, therefore, I have thought quite a lot about the fact that the Science Foundation is really the only existing agency with a broad enough interest to undertake this role.

Mr. MOSHER. This was the question I was going to ask. Do you see NSF as taking a larger role in it?

Dr. HORNIG. I don't want to prejudice the studies which are now underway and which involve quite a lot of people trying to understand in detail what these general concepts they have been discussing translate into terms of potential action, but I think I would say that the simple answer to your question is yes, I think the NSF ought to play a considerably expanded role. The only question is how big and of what nature.

Mr. MOSHER. As a layman and having very little awareness of these matters, I am curious to know what is done with the results of the academic research that the NSF funds. Are the results practically all published in the proper journals and that sort of thing?

Dr. HORNIG. The results are practically all published in journals.

Mr. MOSHER. Then, does NSF take any responsibility for making available the results of the research that it supports?

Dr. HORNIG. It help subsidize journals, for instance, since they don't take advertising for the most part and many of them have trouble keeping alive.

I would like to make one general philosophical statement about science information. Science does not consist of a collection of facts. One of the most important functions is the assimilation of facts in generalizations and boiling them down to ways in which they are useful. Sometimes in thinking of science information, people are inclined to talk as if the problem was just to be sure that all the facts were disseminated. In fact, the Weinberg panel, which studied this matter for the President's Science Advisory Committee made a strong point of the fact that we must in some ways consolidate the information and weed out some of it, even at the very beginning; that it is not a desirable goal for the country simply to get everything written down somewhere. This contributes not only in science but everywhere to these mounds of paper. Someone eventually has to use them. If one fills up, whether it be computing machines or journals, with too much

trivia, one may in effect hide information just as well as if it weren't printed in the first place. So, this takes a lot of careful thought and design.

Mr. DADDARIO. Dr. Weinberg will be a witness, Mr. Mosher, and we can go into this in greater detail at that time.

Mr. Brown.

Mr. BROWN. Dr. Hornig, this may get a little bit off the point, but I have been very much concerned about the broad role of the Federal Government in supporting only certain types of research which is basically mission oriented.

This is true not only of the mission-oriented departments, such as Defense, AEC, and so forth, but it is even true of the National Science Foundation to a considerable extent. There is a trend toward filling in the gaps between what the mission-oriented departments have failed to cover. In a sense, it is still related to a mission. However, historically, before World War II, for example, the net total of basic research in this country was more determined by the decision of individual scientists as to what was important to their science. What contributed to the total of human learning and so forth. I see a particular problem arising right now in that we are failing to move in certain areas where it may be extremely important to the future of the country. For example, there is a rather serious lack of understanding of the way in which people in the world think, or the way they are organized, or the way they are developing. We seem to have spent a great deal of time trying to understand the people of South Vietnam, for example, but there is no research at all on this subject. I am concerned about our present methods of supporting large basic research and the effect it has on this kind of problem. Is there anything that can be done to correct it? I use South Vietnam as only a very small example of this failure to get important knowledge of what is going on in the world that would be important to the United States.

To a considerable extent this may be classified as social research or anthropological science or various other areas of science. I notice in going through your testimony that science seems to be almost synonymous with physics, chemistry, mathematics, and engineering.

Dr. HORNIG. And biology and oceanography.

Mr. BROWN. But the things I am talking about have been substantially neglected—economics, sociology, anthropology, various things of this sort.

Dr. HORNIG. You have asked several separate questions and I will try to take them up one at a time. I don't believe it is a fact that our basic research is being steered by the mission-orientation of the agencies at the present time, at least in the universities. The mechanism by which the NSF, for example, funds basic research is to solicit proposals from the university investigators, which are judged by panels of other scientists.

Mr. BROWN. May I interject at this point, and I know it is a hardship on you, but isn't it true that the proposals that are made by the researchers are at least slanted by what they think is going to be funded in terms of the history of previous funding, and the mission orientation of the panels that are making the decisions?

Dr. HORNIG. It is very hard to talk about what goes on in the minds of people you don't know. I can only state that in the universities

with which I have been associated since the war I saw no evidence whatever that proposals were slanted by what the investigators thought someone was going to say about them.

What does happen is that once a man has written his proposal he decides whether to send it to the NSF or to the DOD, and at this point he certainly gives very careful thought as to who is likely to be interested in it. So there is perhaps a more subtle effect of that sort. But I saw no evidence in any of the universities with which I have been acquainted of people picking their problems because they thought that somebody in Washington would like it that way. This has been true I think, in large part, of the Department of Defense support of basic research as opposed to the much bigger volume of their applied research and developmental activities, which are highly directed.

I think that you raise a very central question in regard to the need to give attention to two different approaches in the selection of topics. One is that at any given time there are topics which are important because the Nation needs to know the answer. The other approach is that which tends to come out of the basic research community as oriented toward the importance of topics in terms of their relation to the science at any given time and topics which contribute most to the fundamental understanding. The NSF certainly has been oriented almost solely, as has a good part of the NIH activities, to this latter role of developing the broad scientific understanding. And the proportion of our research which is basic has actually been rising, in time, very gradually since the last war.

The second question that you raise, of course, is quite separate. You ask about the social sciences, and, of course, I think they deserve your support. But when you ask about Vietnam, for example, you are asking about a practical need of the country. I don't know whether, left to their own devices, the anthropologists would pick Vietnam as a particularly interesting place to study or not. But exactly the point I am making is: There is the decision that an anthropologist would make who is interested in anthropology, and there is the decision that we would make, because we are interested in Vietnam for other reasons.

There is, of course, very extensive support at the moment for research in foreign areas. One of the things that has happened in universities has been the development of Far Eastern programs, of Mideastern programs, of Asiatic study programs, of Russian programs. I can't think of a single major university that hasn't, within the last 10 or 20 years for the most part—some go back much further—developed some of these regional study activities.

There is a division, nevertheless, between natural science and social science, and I am not myself competent to discuss offhand the adequacies of our support for the social science to which you were referring. I am not aware of acute problems, but I think it is certainly something we should look at.

I am not sure whether the National Science Foundation, however, should take on additional responsibilities in this field, particularly in areas involving policy. These problems are sufficiently different from the area of natural sciences around which the National Science Foundation was built that, to me, it would be a serious question whether other public and private organizations shouldn't undertake that primary responsibility.

Mr. BROWN. But why? Isn't the mandate of the National Science Foundation broad enough to encompass the social as well as the natural sciences? Why should we duplicate, or have another foundation parallel the work of the National Science Foundation?

Dr. HORNIG. The Foundation does at the present time support the social sciences to the extent of about $10 million per year, but they are somewhat more concentrated at the experimental end of the spectrum. It is mostly experimental psychology, for example, rather than social psychology, that the Science Foundation supports. I don't know that I can give a simple answer to where the cutoff should come. It is a question of what one interprets basic research in the sciences to be. Our interpretation so far has been to retain the word "science" as applying largely to the natural sciences or the sciences that are related to experiment, though this has moved off some into economics, some into experimental psychology, but, broadly speaking, we have not, as a matter of fact, regarded the social sciences as the central part of what the Science Foundation was intended to do, particularly in examination of policy areas. This intent, of course, could be changed by Congress. My reason for this is simply that it has a very big job to do in the areas in which it is working so well, that the people that would be required to man an effort for the support of a major part of the country's economics, population studies, anthropology, are just a completely different set of people. I think it would be unwise to attenuate the efforts of the Science Foundation at this time unless major new funds were to be provided, and major new organizations, although it might be part of the Science Foundation, were to be set up. I hope you appreciate I am just talking off the top of my head here, and I have not tried to think through this question.

Mr. BROWN. We are dealing with a very basic policy problem here. Frankly I feel that your responsibility as Science Adviser to the President should contemplate some evaluation of policy in this field, and I think your last remark has just indicated what seems to me to be an attitude that has grown up. I will stand subject to correction if it hasn't grown up during this period of governmental support for the natural sciences—an attitude that natural sciences are the sciences, that other fields of science really aren't entitled to full status or stature in the gamut of scientific activities in the world today. There are many other areas which seem to me to need support. The whole problem of pathology in our society today, for example, the problems of criminology and how to deal with them, as far as I know are not receiving the type of attention that is being devoted to what you call the natural sciences. From the standpoint of the health of our society, these are as important today as putting more dollars into high-energy physics. Now this is a policy question admittedly. I am concerned with how these policy questions are going to be resolved at your level, and as far as the functions of the National Science Foundation are concerned.

Dr. HORNIG. If I have given the impression that I think the natural sciences are in any way superior or exclusive, then I did not state my views correctly. But I would say the President has a Council of Economic Advisers, for example.

There are many agencies of the Government concerned with the social sciences, applied and theoretical, so my statement was only

that at the present time my own organization and the organizations we have assembled have their major competence in the national sciences, and this doesn't in any way play down the importance of the social sciences or any of the other areas of the Government. We have in fact been in consultation with the president of the Social Science Research Council trying to explore the question of what needs doing and what possibilities are. I am very much interested in these areas, but I think what I would say for ourselves is we haven't come into any clear focus as to what the proper course of action in the nonnatural science areas is. That in no way is a statement that I consider them less important. I think in fact the situation is they are just beginning to come into their own as sciences, and it is very likely to be true that in the future their role will be much more important relatively than it is now.

Mr. BROWN. You wouldn't recommend that the title of your position be changed to "'Natural' Science Adviser" to the President and the foundation be the Natural Science Foundation, would you?

Dr. HORNIG. I would have no objection if this were really the will of Congress. Seriously though, I would like to make one other point, that one of the key problems in the social sciences, of course, is the number of people available.

Mr. BROWN. In your earlier remarks you indicated that you felt that science was being funded on the basis of the proposals coming in and that there was no bias toward the natural sciences, that the best proposals were being funded in all the sciences.

Now, I would like to know if there is some way of verifying whether or not there has been this impact on those areas which have been funded. Maybe we could perhaps tabulate the number of researchers during the period before the major impact of Government funding took place and after. Has there been a change as a result of the Federal Government's funding during the last 15 years?

Dr. HORNIG. There has not been a major change in the distribution between scientists and nonscientists. One of the very interesting things which emerged from the National Academy's publication of Ph. D.'s between 1920 and the present time is that the proportion of Ph. D's between the science and nonscientific areas has not particularly changed over this whole interval.

Mr. BROWN. By nonscientific areas do you mean the social scientist?

Dr. HORNIG. The breakdown is more than that in the Academy statistics, but between the natural sciences and the rest of the Ph. D.'s there has not been any drastic change in the proportions at all.

Mr. BROWN. I think this is a very significant bit of data bearing on the point we are discussing here.

Dr. HORNIG. I think I would like before answering a question like yours in any great detail to look at the social sciences in the sense that we are now examining some of the natural sciences, which is not in terms of proportions of money spent but whether good people are or are not adequately supported in the work they were doing. For example, again I could only say in the universities with which I have been associated my impression is the standards of support were reasonably good in the social sciences. But this again is a very small personal sample and not a basis for making a general statement.

Mr. BROWN. The things that really are of concern, and I think are of concern to the country, are the problems that we are trying to solve. I think in today's world the social scientists are still going to have to use many of the mathematical and the computer techniques and technologies and many other things, that the physical sciences are using, but they are going to have to apply them to a different set of problems. It is the direction of the problems that we are getting at which is of basic concern to me. I want to know the degree to which this is affected by our scientific support of policies. I hope this will come out more clearly over the course of these hearings.

Dr. HORNIG. I think there should be mentioned, of course, some of the beneficial effects to other fields from Federal support of the growth in natural sciences, which was already before the war beginning to place an inordinate strain on the other resources of the universities. This growth in Federal support of the natural sciences has demonstrably had the effect of freeing up money from other sources, such as foundations and the internal resources of the universities, and it is fairly easy to see that these sources of support have in large measure shifted to the other goals while this process was going on. So it is a very complicated matter. One really does have to look at the funding of research in all areas during the same period that we are talking about here.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have five or six questions which I will try to get through very quickly. As to the budget request, most of the major appropriation bills already have come before the House. Are those bills which have already passed the House below the desired appropriations for research, not just for NSF but for all the agencies?

Dr. HORNIG. I do not know if I can recollect from memory all of the actions. In the case of the HEW appropriation, everything that was asked for has been appropriated. In the case of the Department of Defense, the budget called for something like a 7-percent growth, and I believe that the House action would lower that to about 4- or 5-percent growth. But reprograming, based on the general recommendations of the House, could cause a decrease. In the case of the National Science Foundation, the budget called for approximately a 50-percent growth in the basic research component.

Mr. VIVIAN. You said 50 percent?

Dr. HORNIG. Fifty. And the House action cut that to about a 25-percent increase in the basic research component. Of course, reprograming is possible, and the Senate has not acted. I think, except for this NSF action, the cuts have been small, but they have all been in the direction of cutting back on the budget. Of course, although these budget cuts in the other agencies appear to have a small effect on the overall totals, they are large in terms of the growth rate and we would not like to see the support of basic research in universities stagnate in these agencies.

Mr. VIVIAN. That is true of many other budget items as well, the trend is generally toward cutting back?

Dr. HORNIG. Yes. Basic research in all the mission agencies is buried in very many budget items, and it doesn't always appear as

explicit items. There is also the question of what reprograming will occur after the budget action.

Mr. VIVIAN. For example, the NASA budget has not been cut substantially. You suggest that the NSF budget is the only one that has been materially cut, and this primarily in the basic-research support in which 50-percent increase was requested?

Dr. HORNIG. That is substantially correct.

Mr. VIVIAN. Let me switch to a second question. Relative to the distribution of scientific information, the National Science Foundation has a certain goal and is active in it. The Department of Commerce is also interested in a bill, which I am sure you are aware of, regarding State-Federal technology centers. To what extent is this in conflict with the interests of the National Science Foundation, or to what extent has this been so examined by your Office as between the two agencies?

Dr. HORNIG. I do not think there is any conflict whatever with the National Science Foundation's activities. That bill is designed to get technical information into the hands of local industry. It is a dissemination activity primarily. I think the Foundation's primary role is in the design and evolution of information systems in a much more general sense.

Mr. VIVIAN. In other words, you do not construe the National Science Foundation to be in the role of disseminating information?

Dr. HORNIG. I don't see why it should; no.

Mr. VIVIAN. There is no conflict at the level of your Office in these bills?

Dr. HORNIG. There is no conflict.

Mr. VIVIAN. On page 7 of your testimony, approximately the 10th line down, is the statement:

> It also permits the Foundation to take the lead, when requested by the Office of Science and Technology, in organizing and carrying out interagency studies and evaluations.

Can you give me some examples of those interagency studies and evaluations? Three or four will be sufficient.

Dr. HORNIG. A recent one, which I mentioned elsewhere in my testimony, was after the submission by the Academy of the ground-based astronomy report; the Science Foundation undertook, working together with the other agencies, to assess what the plans of NASA, DOD, and everyone else were in this area, with a view to seeing what the national ability to implement these recommendations might be.

Now, as a smaller example, in the scientific information area, the Science Foundation, at our request, took the lead in bringing the NIH, DOD, and themselves together in supporting the Chemical Abstracts proposal for developing a mechanized information system for chemical information.

The NSF has taken the lead in the upper mantel project for coordination of the geophysical research on the earth's crust.

It has taken the lead, and is still continuing a study, on university computers. This is becoming, I might say, a very major problem because the demand for computers is so great, and they are so obviously an essential item to science and technology and its future, that there are real questions as to how they should be supplied and how they

should be funded when they are in universities. This is another area in which the NSF has taken the lead.

Still another I can think of is with respect to the science information exchange, which is funded by the NSF but which serves all the agencies. NSF is undertaking a study now of user needs, because one of the real problems in all science information activities is to couple, if you like, the technology of the information specialist to the needs of the people who use it.

Mr. VIVIAN. Supposing we take atmospheric research, for example, in which all the other groups are very active. Has NSF here had any significant role in coordination?

Dr. HORNIG. Here the main coordination has taken place in the Interagency Committee on the Atmospheric Sciences on which the NSF is a very important member.

Mr. VIVIAN. Why should that be handled differently than these other matters?

Dr. HORNIG. For one thing, because NSF is a minor partner in the total funding, on the one hand, and, secondly, it is coupled tightly to a very big operational program: the weather services of the country. I should mention that is not unique. Oceanography is another similar case. This is coordinated among the agencies by the Interagency Committee on Oceanography on which NSF is a very important member. NSF, in fact, plays the key role in the support of oceanography as science, but it is supported for many other purposes. It does not play the leading role in determining the role of oceanography in what I would call, if not nonscientific, at least applied scientific aspects. I think that tends to be the pattern—that, where it concerns principally basic science or science education, NSF plays the lead role.

Mr. VIVIAN. I want to come back to what I think is underlying so much of this. As I understand the structure, you are the chairman of the President's Science Advisory Committee; is that a correct statement?

Dr. HORNIG. I am the Chairman of that Committee, but by election by the Committee. Just for information, this is a debate the Committee has every year.

Mr. VIVIAN. I can understand that. You are appointed directly by the President, and you report to him, whereas the Director of the National Science Foundation reports directly to a board. That Board is appointed by the President, and the appointment of the Director is also a Presidential appointment; but, after being appointed, the Director reports to the Board; is that correct?

Dr. HORNIG. That is correct.

Mr. VIVIAN. In other words, the reporting chain differs in that Dr. Haworth reports to the Board which is, shall we say, the top ceiling, whereas in your own case you report to the President?

Dr. HORNIG. That isn't quite correct. Let's put it this way. Dr. Haworth is responsible to the Board, but he certainly reports directly to the President in administrative matters. The Board is responsible for setting broad policies for the Foundation, and in that sense he is responsible to them.

Mr. VIVIAN. I am not here for the purpose of embarrassing either of you gentlemen. So far as I can determine, the so-called PSAC committee does not interweave itself between you and the President

whereas the NSF Board could be construed as so doing in the case of Dr. Haworth. Then, another vein of this, that particular Board is composed, I believe, of primarily academic personnel—that is, persons derived from academic background. Is that a correct statement?

Dr. HORNIG. The majority of the Board is; yes.

Mr. VIVIAN. It is often labeled as the "big university committee," as I am sure you are well aware. If it had a coordinated role through all of science, through the many missions and agencies, and if it were comprised of people primarily from the big universities—which it is—then, it would have a rather peculiar role relating to science and national defense. Doesn't the change which established your office reflect the fact that the Board didn't necessarily reflect the interests of persons engaged in Defense Department research, or persons engaged in NASA research, or persons engaged in NIH research, but it reflected the interests of the major universities? In other words, didn't the existence of the Board obviate the possibility that NSF could carry out its initial functions?

Dr. HORNIG. I do not think I would quite agree with that analysis, in that the central function of NSF was defined in the first place as the health of basic research and science education in this country. This was its main mission in life. The Board I think has been excellently suited for carrying that out.

It was also assigned the responsibility for setting broad science policy for the whole Government and evaluating the programs of other agencies. I believe this was a secondary intent of the Congress and not the central one. I think there are a whole complex of factors that make NSF not suited to evaluating, for instance, the military development programs of the Department of Defense, of which the composition of the Board is only one of the minor ones.

Mr. VIVIAN. It was my impression that it was the intention of Congress that the setting of policy was to be a very important step, and that this has been found to be an untenable position. And, being untenable, a new approach was followed.

There have been many questions that have related to the interrelationship between these various offices. I must admit I am more satisfied with the present arrangement than the previous one, but the interrelationship is far from clear. As I have read the testimony, I am left with the conclusion that if I were in the position of the Director, as Dr. Haworth is, I would sometimes not quite know what I shouldn't do. In fact, I would frequently not know what I shouldn't do, except I would have tested out these endeavors in the hard course of ordinary life and discovered that some got me in trouble, much more trouble than others, and I would leave those alone. I would say that the policy statements and words are downright meaningless.

Let me go on.

Mr. DADDARIO. You don't want an answer to that last question?

Mr. VIVIAN. I don't think anyone here would like to answer it.

I would like to go on to another matter, the international role of the United States in science. As far as I can tell, the National Science Foundation is only marginally engaged in sponsoring science on an international basis; that is, sponsoring scientific work elsewhere, with the exception of some of the special programs such as IGY. The Office of Aerospace Research of the Air Force has a large-scale role

in international science. I base this partly on reading the reports of OAR and being at its conferences. The Department of State seems to have a much smaller role. Is your office personally concerned with the international role of the United States in science? Is this part of its purview or not?

Dr. HORNIG. Yes.

Mr. VIVIAN. Is there any policy statement which has been established as to the relative role of these several agencies in sciences internationally?

Dr. HORNIG. Well, there is a general statement that all of the international activities will be overseen in a general way by the Department of State.

There are many kinds of international activities, and I am not sure what kind of a general statement one would make. There are the kinds of things we do internationally in science in pursuit of nonscientific foreign policy objectives of the United States. There are ones that are aimed at securing general international cooperation. There are the ones which are concerned with utilizing foreign scientific capabilities to supplement our own in some areas. After the war for a while this sort of foreign science assumed some of the facets of Marshall plan aid. So, there are many kinds of objectives.

Mr. VIVIAN. Let me go to a particular one. There are many others that I am very interested in, including those referred to a moment earlier by Mr. Brown, but one particular one is personally interesting to me. I refer to having a major international role played in the future Voyager system to Mars, since I believe this is one of the better ways of generating a scientific program, where there can be no military arguments brought out. In my discussions with NASA people during the budget hearings, I asked questions about this, and the answer was that this was not their purview. I have the feeling if I were to ask the Department of State, they would say that this is not within their purview. I think I could give a long list of agencies of whom I could ask that question, all of which would say it is not their responsibility. Now, is it your responsibility?

Dr. HORNIG. I am interested and concerned. Yes, I suppose it is my responsibility.

Mr. VIVIAN. And no one else's, at least not directly?

Dr. HORNIG. Well, NASA has very extensive international programs. I would not like here to take issue with them without having explored the matter. It is not quite clear to me why this matter is not also of interest to their international division.

Mr. VIVIAN. In other words, the international division of NASA would be authorized to establish a policy relating to this particular item?

Dr. HORNIG. I am afraid I am not prepared to comment offhand on the internal structure of NASA, but certainly international cooperation has been one of their goals in the space program, and they have established very extensive programs in international cooperation with respect to other programs.

Mr. VIVIAN. This did not require the initial authority of your own office?

Dr. HORNIG. Not on individual programs, certainly not.

Mr. VIVIAN. Fine. Thank you. I have no other questions Mr. Chairman.

Mr. DADDARIO. Dr. Hornig, did you want to say something further on that?

Dr. HORNIG. With respect to the question I didn't answer, I would like to get emphatically on the record that OST, in general, does not interpose itself between the heads of agencies and the President. I mean we are basically a staff office to the President; so, the administrative lines reach from the heads of agencies directly to the President. That is all.

Mr. YEAGER. One question, Dr. Hornig: In connection with the 15-percent increase in the Federal sponsorship for basic research which has been suggested to us by the academy and I believe by Dr. Haworth, and I think you have mentioned it. If it becomes a national policy to increase this by 15 percent a year, and if the source of funding from private, statewide and other sources doesn't keep pace with this—and my understanding is that this is at the rate of something like 5 or 6 percent a year—if this goes over a long enough period of time, don't you arrive at a situation where the Federal funding in the universities constantly increases in proportion so that you might have what some people have referred to as Federal universities? Do you see this as a danger, and should this be reviewed after a period of time to see whether this percentage arrangement really ought to be continued?

Dr. HORNIG. You have asked several questions. In the first place, we have not taken the position that it should grow at 15 percent a year for many years into the future. The position in our case was only taken for this year and based on facts available for this year. To look ahead further is one of the central purposes of the study I mentioned that we are currently carrying out, because the arguments need considerable analysis and refining. So I have no position at the moment on 15 percent per year into the future.

As to the effect of increased Federal funding on the universities, there are obvious dangers, because with funding there is always the possibility of control. But up until now I would say that effect has been a very healthy one. There have been problems, but the problems have been worked out. I think the universities have retained their independence in the scientific area. I think the general vitality of science in America exceeds that of any other place I have seen. During the very period under discussion, this has been a period of scientific flowering in America. Nonetheless, the problems you raise are real ones and it is therefore going to require continued good sense and attention by the executive, the Congress and by the universities themselves, in fact by the whole community.

Mr. YEAGER. So you would go slow in establishing a national policy on this basis or attempting to establish for an indefinite period of time any given percentage increase?

Dr. HORNIG. I think the statement about a percentage increase is just too narrow a statement of a plan. One doesn't increase everything certainly at that rate. I am certain there is no policy ever going to be generated that says increase everything by 15 percent. The minute you get beyond that, you talk about the evolving structure and needs, which is a much broader discussion.

Mr. VIVIAN. Mr. Chairman, I have a very broad remark to make on the subject that has just been brought out. I have had experience with persons complaining because of greatly increased Federal support for a wide variety of activities in modern life. I am forced to remind them that State legislatures have never been proscribed from providing more support for universities, in my State they do; they have never been proscribed from providing support for water pollution control measures, which they have never done, and I can give you a whole list.

Mr. DADDARIO. Dr. Hornig, we have some questions which I hope we will be able to send to you for the record.[1]

Dr. HORNIG. I would be happy to answer them best I can.

Mr. DADDARIO. I would like to add one item with reference to this last point which was raised, and I am inclined to agree very strongly with Mr. Vivian, I see in your statement where you say "taking into consideration other sources of support," that you are aware of this, too. View the entire situation, not only what is being done in the Federal area, but also what is being done by the States, what is being done privately. In the final analysis it is how they work together that is important. I note in your statement also that you refer to NSF as a "balance wheel."

It is my feeling that you meant it in this way.

Dr. HORNIG. I think that your statement is quite correct. When I say NSF should act as a balance wheel, I, of course, no not mean in any sense that it should be a responder to what everyone else does.

I hope, intellectually, that it will provide leadership. In the sense you mentioned that must mean balance wheel.

Mr. DADDARIO. Yes.

Thank you, Dr. Hornig.

This committee will adjourn until 10 o'clock tomorrow morning at this same place.

(Whereupon, at 12:20 o'clock, the committee was adjourned to reconvene at 10 o'clock, Wednesday, June 30, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JUNE 30, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. The meeting will come to order.

Our first witness this morning is Dr. Frederick Seitz, President of the National Academy of Sciences.

Dr. Seitz, we are pleased to have you here. We would appreciate it if you would proceed with your statement.

STATEMENT OF DR. FREDERICK SEITZ, PRESIDENT, NATIONAL ACADEMY OF SCIENCES

Dr. SEITZ. Thank you, Mr. Daddario.

Gentlemen: In appearing before you today as President of the National Academy of Sciences in connection with your review of the National Science Foundation, I would like to focus attention on three matters. First, on the deep importance of the National Science Foundation to science in our country as a symbol of our national maturity as well as a source of funds for science. Second, on the close relationships which the National Academy of Sciences has had with the National Science Foundation. In fact, these associations date back to a time before the Foundation was given official status. And finally, on the Foundation's foreign activities which are closely related to the interests of the National Academy of Sciences.

Whenever the status of the National Science Foundation is under review, it is important to realize that it is at present a unique Federal agency, having no counterpart. Its main goal is the support of basic sciences, quite independent of any immediate practical goal or mission the sciences supported may have. Thus the position of the National Science Foundation is quite different from that of the National Institutes of Health or the agencies of the Department of Defense, the Atomic Energy Commission, and the National Aeronautics and Space Administration which support research. In creating the National Science Foundation our Federal Government for the first time gave official recognition to the fact that general basic natural science is sufficiently important to the national welfare, inde-

pendent of the immediate foreseeable practical results which may emerge from science, to merit Federal financial support. The creation of the National Science Foundation indicated that our country had finally become of age in the era of science. In the appreciation of science as a social force, we had finally pulled completely abreast of our European cousins after lagging since our country was founded.

I would like now to paraphrase several pages of historical material which I think is worth emphasizing at least once in these hearings. Science, as we know it today we call Western science although it is becoming worldwide, has grown through evolution, somewhat like a biological evolution, the evolution of man or some other biological organism, and that evolution has extended over about 5,000 years. Most of the great civilizations of the past which feed into our own have had some body of knowledge that can be called science in their terms, usually centered about studies of the physical world in which we live, and it was usually either used for religious or technical purposes.

We look at what might be called the science of most of the older civilizations, however, we find it surrounded by mysticism and often superstition, although some remarkable results were obtained. As you know, some of the ancient calendars are even more accurate than the one we use every day for normal household purposes. The first time in this stage of evolution that science began to resemble something that we today call science occurs in the Greek civilization. The Greeks starting about 1,500 years ago focused on what we call science, and were remarkably successful. All of us study Euclidian geometry when we are in high school, it is a very eloquent, logical body of scientific nature. They had a number of other successes, the work of Archimedes on floating bodies and some astronomical success.

However, the Greeks in their approach to science had two major drawbacks which we can recognize clearly today with the advantage of hindsight in our own successes. There was a tendency for pure speculation to overrule observation. In other words, they never tied theory and experiment successfully closely together. They tended to give priority to the views and opinions of great men rather than to what they saw and measured.

In the second place, the society in which the Greek scientist lived did not really appreciate the realities of science. They admired the wisdom of the men but they did not appreciate how useful science would be in everyday engineering problems. Had they appreciated this the history of the world may have been quite different. Our ancestors in Western Europe brought science back to attention in the 15th and 16th centuries. They were, of course, stimulated by reading the Greek scientific books, and they were greatly affected by them, but they induced a quite different spirit in the attitudes toward science stemming from the fact that both the scholars of those days and the nobility had very deep practical roots, they were close to the soil and they were looking for things that would be useful in everyday living. They had three new concepts, speaking broadly.

First, they recognized that if they were to make progress they had to tie experiment and theory together very tightly and let theory be guided by experiment rather than by the minds of men alone. This is the first important principle, that you let your general decisions

be determined by what you see and can measure. It accelerated measurement.

Second, they realized that science could have great practical results. If you examine the writings of the great minds who reflected on science between 1400 and 1600, you will find a whole sequence of men, there is Nicholas of Cusa, one of the early scientific philosophers, there is Galileo, Francis Bacon, they all emphasized that if we learn enough about nature we can use it and bring about a revolution and a way of living, get new tools.

And finally—this is the point I want to emphasize particularly—they recognized that while they were squeezing this body of knowledge in order to get practical results they had to support science for its own sake if they were to build up a body of science that would be complete and general.

I turn now to my text, page 4.

One cannot emphasize too strongly that a very important feature of the great tradition of European science—and here I use "European" in such a way as to exclude "American" for the moment—is that it has placed a high value on knowledge derived for its own sake. The Europeans realized very early that one could not expect to foresee the applications which would inevitably come once one had sufficiently profound knowledge of a field of natural science. This principle was used steadfastly by the Europeans, along with good practical judgment, for many centuries. It was this aspect of their approach to science which eventually made it possible for the Western Europeans to create the worldwide technological revolution of which we are so keenly conscious today. It was this point of view which led to marvels such as antibiotics, atomic energy, and Telstar. Had the Europeans invested their resources only in goals having immediate practical importance, we would be living in a much more primitive world.

The early settlers in our own country, facing an enormous untamed wilderness, had too many hard practical problems to deal with to do much about the expansion of knowledge for its own sake. Instead they focused on the practical consequences of science and were willing to let the Europeans generate the basic knowledge which made the development of science possible. This attitude dominated our scene well into the present century, making us primarily users rather than generators of basic knowledge until quite recently. We produced many great engineers of many varieties ranging from those who built the Panama Canal to inventive geniuses such as Thomas Edison. But until recently we added relatively little to the great body of basic scientific knowledge, which is one of mankind's richest treasures.

Fortunately, the seeds of appreciation of the techniques of generating new basic knowledge were planted very early in our country, as we know from the work of men such as Franklin and Jefferson. As our level of income and our freedom from hardships increased, the desire to speculate on nature began to grow and mature. By the time of World War II we had, particularly in our universities, developed a respectable capacity for basic research, funded in the main through private and State sources.

In fact, this capacity had grown to such an extent by 1940 that it proved to be a critical asset in our conduct of the war and gave our country a new and dramatic realization of what both science and the well-trained scientist could mean to the national welfare. It was this appreciation which led Vannevar Bush and his colleagues to propose in 1945 that the Federal Government create an agency which would support basic science without explicit reference to pre-assigned practical missions and take a place alongside the practically oriented agencies. In taking this step, our American society finally caught up with its European cousins in its appreciation of how to optimize the benefits to be derived from science.

Perhaps the following point of view represents one way of emphasizing the importance of the National Science Foundation in relation to our national welfare:

The creation of the Foundation in 1950 emerged from the realization that our Nation had achieved scientific maturity. The sense of responsibility associated with that maturity required that some of the Federal money to be used for basic science be free from immediate practical restraints. If our Nation values its position among those who lead in science, it must expect to support the National Science Foundation in a balanced and rational way.

In discussing the various categories of program which the Science Foundation supports, each scientist will naturally emphasize somewhat different aspects of that program and the budget associated with it as a reflection of his own interests. I do not desire to underscore my own view at this point in the present discussion. It should be emphasized, however, that the administrators within the National Science Foundation draw advice from a large part of the scientific community when developing the programs and budgets which they propose for the Foundation.

My greatest wish is that when the congressional committees weigh the various components which make up the budget of the Foundation, they will seek advice of the scientific community before giving preference to one component of the proposed budget over another.

I should like to turn next to a discussion of the close relationships which have existed between the National Academy of Sciences and the National Science Foundation over the entire history of the latter. In fact I might point out at the start that the scientific leaders who urged the creation of the National Science Foundation at the end of the war were, for the most part, closely associated with the National Academy of Sciences and had served at various times in their careers in a major way in the activities of the Academy. Still further, my predecessor as President of the Academy, Dr. Bronk, was a member of the first Science Board of the Foundation and was its Chairman for a number of years.

Thus the Academy has had a deep interest in the welfare of the National Science Foundation and its programs from the initiation of the latter. To complement this, the Science Foundation has, throughout its history, supported the Academy in its official position as adviser to our Government whenever the issues involved in our advisory work have been closely parallel to the programs of the Foundation.

It would take me a very long time to describe in any degree of detail all the programs in which the Science Foundation and the Academy have worked in close cooperation. As a result, I shall take some of the larger and more dramatic instances. The following cases deserve specific mention:

Mr. DADDARIO. Before you get into these, I wonder if you could go a bit further into the relationship which exists between your organization and the National Science Foundation. You stress that Dr. Bronk was a member of the first National Science Board and was its Chairman for a number of years. Should it be this way? Should there be this close relationship, or would it be more valuable to the Academy and the National Science Foundation to be distantly separated? Would this assure more objectivity?

Dr. SEITZ. I don't have any strong opinion on that, Mr. Chairman. I think that during the period of growth of the Foundation there was a considerable value in having that close tie. At the present time, we have excellent working relations, what might be called at the staff level, and when matters require decisions somewhere near the top, we have a meeting with the Directors of the Foundation and some of the people who work with him in his executive office to straighten out the details and set policy, and that works very well. At present I don't see any rigid need for a tie in an ex officio basis because we do have good relationships.

Mr. DADDARIO. You have said that the congressional committees should seek the advice of a scientific community before giving preference to one component of the Foundation's program over another. Do you believe that the close relationship which the Academy has with the National Science Foundation is a good way to formulate this opinion, and a good source for the Congress to look to as it seeks advice?

Dr. SEITZ. It is one of the good sources.

Mr. DADDARIO. The fact that you do have people on the National Science Board allows the Board to sort of act as a bridge across which some of this advice can come: that is, from the Academy to the National Science Foundation and then to the Congress?

Dr. SEITZ. Yes. Several members of the Council of the Academy and also the Committee on Science and Public Policy serve with the Science Board of the Foundation. I reviewed this matter with the Director of the Foundation, for example, before we appointed Dr. Brooks. And he felt there was no conflict of interest as long as the issues discussed were general policy matters, that affected the welfare of American science as a whole.

Mr. DADDARIO. So if there are matters which you believe affect public policy and questions of appointments, this is discussed and determinations are made which in your opinion, at least, is in the best interest of the entire scientific community?

Dr. SEITZ. That is right. The present working relationships, in which we have no ex officio representation on the Science Board, are working well.

Mr. ROUSH. Are you suggesting by your statement that your greatest wish is that the committees of Congress use the scientific community, and that we are not adequately now using the scientific community in making decisions which relate to areas of science?

Dr. SEITZ. Well, I have felt over the years that the Science Foundation has generally presented what I might call balanced budgets to the Congress, and naturally the overall sum has to be determined by the state of our economy and things of that kind, but there have been occasions when one part of the budget was given preference over another, and I feel that it would be wise to have some consultation with the scientific community at such times, that the decisions affecting the balance of the budget of the Foundation ought in general reflect the opinions of the scientific community as well as they must the opinions of those in Congress who sit on the committees.

Mr. ROUSH. I think we would agree with you on the importance of the Congress consulting with the scientific community in reviewing a matter such as the budget of the Foundation. You have indicated the Foundation has consulted with the scientific community through the National Academy of Sciences in preparing its budget. Are we then not duplicating what the Foundation has already done if we proceed to consult again with the Academy on the same matter?

In other words, would we receive new information?

Dr. SEITZ. One might get points of view that hadn't been completely stressed. I think it depends on the instance.

Mr. BROWN. Let me ask this: Is the National Academy of Sciences necessarily the only spokesman for the scientific community?

Dr. SEITZ. No; far from it, we are just one of a number.

Mr. BROWN. Is it then possible that perhaps Congress should broaden its search for a voice from the scientific community beyond that which the Academy might represent?

Dr. SEITZ. Yes. I think I would emphasize the value of a plurality of opinions. We try to be right in rendering advice in the Academy. We do our best, but we recognize that there are members in the scientific community that sometimes have different views and they should be heard.

Mr. BROWN. I must confess that I don't have a complete understanding of just what constitutes the scientific community, and who might constitute its authorized spokesman. Perhaps we ought also to explore that in a little more detail during the course of these hearings. That is all that I have right now.

Mr. DADDARIO. Any further questions at this point?

Will you proceed, please, Dr. Seitz.

Dr. SEITZ. I might mention the following items in which we have worked very closely in cooperation with the Foundation. There is the International Geophysical Year. It was an 18-month study, extending from July 1957, through December 1958, of geophysical phenomena associated with the solid earth, the earth's surface, and the atmosphere. It was conducted during a period of relatively strong solar activity, when the disturbing effects of the sun on the earth's magnetic field and atmosphere are at a maximum. The program was carried out on a worldwide basis with the cooperation of the scientists of some 66 countries having scientific facilities for geophysical research. Planning of the U.S. participation, and the conduct of our ties with the efforts of the other countries, were the responsibility of a group of distinguished scientists appointed by the Academy. The program was one of unprecedented scope in international science. It could not have been carried forward without the

fullest participation of the Federal Government, both in its scientific planning and execution and in its financial support.

The National Science Foundation was the focal point for the Government's massive effort in support of the IGY. While hundreds of scientists from every part of the United States were involved, the large burden of scientific staff work that made their efforts fruitful was carried by the professional staffs of the Foundation and the Academy. The IGY represented a new level of cooperation in basic science between governmental and nongovernmental agencies and institutions. The partnership of the Foundation and the Academy was essential to its success. Very great benefits to science and our understanding of our environment resulted, which have led to major further international cooperative efforts such as those of the International Years of the Quiet Sun, now in progress during a period of minimum solar activity (calendar years 1964 and 1965).

This Committee of the Academy is perhaps best known to Members of the Congress because of the recent report, "Basic Research and National Goals," prepared under its direction in response to a request addressed to the Academy by the House Committee on Science and Astronautics through its Subcommittee on Science, Research, and Development.

A number of other important studies have been prepared by the Committee on Science and Public Policy, which was established by the Academy in 1962 on the recommendation of Dr. Detlev W. Bronk and Dr. George B. Kistiakowsky. They saw the need for a committee that could provide leadership in the analysis of the status and needs of broad fields of science, and could advise the Federal Government or others on the most promising directions for future research. Some of the funds for these studies have come from nongovernmental sources, including the Ford Foundation, the Sloan Foundation, the American Chemical Society, and the Population Council, but the major portion of the Committee's support has been provided by the National Science Foundation, which is deeply interested in the outcome of such reviews. The Foundation has followed closely the Committee's study of Federal policies and practices in the support of basic research in institutions of higher learning and its reviews of facilities needs for ground-based astronomy, of the uses of computers in universities and colleges, and of needs and opportunities in the fields of chemistry and physics. Similar undertakings are being planned in mathematics and biology. Conducted by panels of specialists in whatever field is involved, and critically reviewed by the Committee on Science and Public Policy, such studies are designed to bring before the Foundation, or other agencies, the carefully considered views of the scientists with regard to the needs, opportunities, and relative priorities in each field on which attention is focused.

The suggestion that it would be desirable to drill deeply into the earth's crust with the hope of obtaining fundamental scientific information concerning the transition between the crust and the mantle was first made by an informal group of earth scientists who were later organized as a committee of the National Academy of Sciences. The National Science Foundation took a major interest in the program from the outset and provided funds and support for the first

experimental drilling in the deep ocean, which was carried out off the coast of lower California under the closely shared jointly responsibility of the Foundation and the Academy.

In the period since 1961, when the first phase of this program was completed, the National Science Foundation has taken over full operational responsibility and the Academy has resumed its more traditional position of serving as a scientific and technical adviser on appropriate aspects of the undertaking.

Both the Foundation and the Academy have been interested in the evolution of reference tables of scientific and engineering data from which investigators and engineers can obtain authoritative current summaries of available data. With the Foundation's support the Academy has been able to call upon the advice of leaders in the several fields of science and technology involved.

Out of this joint interest and endeavor has recently evolved the new and highly important national standard reference data program of the National Bureau of Standards, to which the Academy is engaged in a study of this subject in order to determine how efforts can best be directed toward the realization of practical systems.

Mr. VIVIAN. I would like the privilege of interfering with the smooth continuation of our speaker's efforts on this particular subject. It is of particular interest to me.

As a person who has learned several languages, poorly, I must admit for the purposes of translating foreign scientific journals, I am well aware of the need for efforts such as you are proposing. However, I think perhaps it would be well if you would go beyond this step. It is not just a question, in my mind, of translating a particular language, I think there is possibly a much greater step which the field of science can take and which may have a future impact on the field of international relations. This is what I will call the continuation of the fond and faithful hope which Esperanto represented; namely, that there would be an international language. The evidence of nationalism throughout the world suggests that it will not be an easy task. But fortunately we may be able to refer to the new god of science to establish a new language, because certain of the languages of the world are far more easily automatically translatable than others. In particular, if we could arrive at a tonal system, that is to say an alphabet which was more uniquely distinguishable by automatic detection devices, in other words, pattern recognizers or correlation devices, we could almost surely arrive at a language which was not only automatically translatable with fair ease, but also which would be fairly easily automatically transcribed. I must admit we might lose a certain fraction of our employed people by no longer requiring stenotypists and secretaries but we could at least conceivably reduce enormously the number of people engaged in the sheer handling of words.

I think this is a realistic possibility which could have enormous impact on international affairs. If we could convince people, for example, in French Canada that the retention of the French language is no longer the maximum goal of life, or people of the Far East that their own dialects are no longer the maximum requirement of welfare, we might conceivably use, as I say, the pressure of science to break down some of the most troublesome international problems.

This is obviously a task that will not be accomplished in 5 years or perhaps even 50, but it does have significant economic value and it does have significant international value. I would only comment that if the National Science Academy could in some way promote the establishment of a new machine translatable alphabet and language, it might accomplish a very great benefit for all of us. It would then be up to those of us who are in Congress to find some way to induce large portions of the world to learn this language. I think the fastest way to induce them to learn this new language is to have a machine with an on-off switch that is capable of replacing—I hesitate to say secretary, because that brings into mind the image of an attractive secretary and this might not be replaceable—but replacing much of the very expensive and basically unproductive clerical machinery of offices throughout the world. That is a sufficient comment for the moment. Thank you.

Mr. WAGGONNER. I have one comment, Mr. Chairman.

I think this would require more than that complicated machinery, and he is quite optimistic if it can be done in 200 years.

Mr. VIVIAN. I think it is technically feasible in 3 or 4 years, but I don't think it is internationally feasible within that time.

Dr. SEITZ. As you know, there is a great deal of interest in translation on the part of companies which developed computers. We are still at the crawling stage. We are trying to decide in what direction we shall walk when we can walk.

Mr. VIVIAN. But generally the languages are inappropriate for the tasks being proposed.

Mr. DADDARIO. Have you gone as far as you need to go on that subject?

Mr. VIVIAN. I think if I can only plant the idea successfully, it may have fruition 4 years from now.

Dr. SEITZ. Normally, in the Academy, when someone delivers an opinion such as that we soon put them on a committee.

Mr. VIVIAN. I am safe.

Mr. DADDARIO. I can see no reason why Mr. Vivian could not serve on such a committee.

Dr. SEITZ. I will keep that in mind.

The Foundation conducts extensive fellowship programs that have enormous importance for the health and steady progress of science. In addition, the able staff of the Foundation carries on a program of analytical studies of the way in which trained manpower and financial resources are distributed and employed in the structure of our scientific and technological endeavor. Although the Foundation must incorporate within its own offices a strong staff for the study of the professional training and development of scientific investigators, it looks to the Academy, which has had long experience in the evaluation of fellowship applications, to maintain a study of selection techniques and to mobilize leading scientists and engineers in widely representative reviewing committees to advise on the actual selections. At the present time, the Academy, each year, draws several hundred scientists and engineers into this crucial task.

A number of fields of science deserve continuing study by a committee because they are in a state of rapid evolution and require

program guidance. In many cases the National Science Foundation has called upon the Academy to establish and sustain such committees. Whenever this is done, the staff of the Foundation works in close cooperation with the Academy to determine the general way in which the study should be carried out. Examples include the Committee on Polar Research, the Committee on Atmospheric Sciences and its Panel on Weather and Climate Modification, the Committee on Radiofrequency Requirements for Scientific Research, the Committee on Fire Research, the Committee on the Alaska Earthquake, the Committee on Water, and the Space Science Board.

The Space Science Board works closely with NASA, of course.

Let me turn next to international science.

The Foundation and the Academy form a partnership in the study and development of many international scientific programs, collaborating so as to provide both structure and substance to the role that American scientists and scientific institutions play in international scientific affairs. The benefits to American science derived from this partnership are numerous, varied, and in some respects subtle. Taken collectively they are significant in helping to assure that our Nation occupies a position among the leaders in international scientific affairs.

Viewed broadly there are three well-established categories of collaboration between the Foundation and the Academy in international matters:

1. To individual American scientists perhaps the most important cooperative endeavor is the one which centers about the support of international scientific conferences and related programs that are carried on under the formal direction of the various international scientific organizations both governmental and nongovernmental. In this category are included matters ranging from travel grants for individual scientists who participate in international scientific conferences to the planning and execution of our national contributions to the major international scientific programs such as that of the International Geophysical Year, the International Biological Program, and the International Indian Ocean Expedition.

2. The second area of collaboration arises from the common concern of the Foundation and the Academy for the management of international scientific activity in order to provide reasonable assurance that the maximum benefits will be derived from the time and money spent on such work. Thus the Foundation provides financial support on shares with the Academy in scientific support of the U.S. national committees of the several international scientific unions, and of various special international groups such as the Scientific Committee on Antarctic Research and the Scientific Committee on Oceanic Research.

3. Finally, the Foundation and the Academy join in the conduct of scientific exchange activities with the academies of the Soviet Union and some of the eastern European nations. Since such programs are closely linked to matters of official foreign policy, the Department of State enters as a third partner in the planning and development of programs of this type. The program of exchange with the Soviet Union is now in its sixth year. It has not only helped

in the establishment of closer working relations between the United States and Soviet scientists, but has also given us a degree of hope that Soviet-United States scientific relations will eventually come to resemble those among the open nations of the world.

Mr. DADDARIO. Dr. Seitz, on the first page of your statement you refer to the fact that the National Science Foundation's

main goal is the support of the basic science quite apart from any practical goals or mission that the sciences supported may have.

Have we reached the point in the growth of the National Science Foundation that it ought also to become involved with the practical applications of this knowledge?

Would you give us your view on that?

Dr. SEITZ. I would put it this way. I personally would not like to see the Foundation's program determined in any massive way by immediate practical programs, for example, by some of the needs of the Atomic Energy Commission or the Department of Defense. On the other hand, I think it would be beneficial for the various agencies to have channels of communications of such a type, for example, the Department of Defense would very early know of results that come out of the work supported by the Foundation that could be of use to the agencies which have applied missions. Actually, that is being done on the whole quite well. Organizations like the Office of Naval Research which would historically have close ties with the Foundation do keep an eye on the activities of the Foundation. There are many, many informal connections. I think the main thing I would say is I wouldn't like to see a radical change in the policies governing the support of the Foundation as a result of pressure in applied work. I think we would lose something else.

Mr. DADDARIO. If we are to confine ourselves for the moment to the National Science Foundation continuing to work in the basic research area, you indicate that the transfer of the knowledge to the mission-oriented agencies could be improved. Would you go into that further?

Dr. SEITZ. I will put it this way. I think the staff of the Foundation itself is excellent, do their job as well as they can within the ordinary human limitations. What I think is needed in order to make certain that we get the maximum practical results out of the Foundation is to make sure that the agencies with missions keep strong groups within them that are knowledgeable in the areas of basic science. You sometimes hear it said that perhaps we ought to give responsibility for all the basic science to the Science Foundation. I think that would be a mistake. I think the Department of Defense needs people in it who have programs of superiority for areas of basic science that definitely have applied interests to the Department of Defense, the same within the NIH, NASA, and so forth, so that they will have bodies of people who will recognize quickly discoveries that are made, for example, by those supported by the Science Foundation that are important to their missions. I don't think we should try to tie all of the basic work to the Foundation itself. We should keep it strong in this mission of evolving science but also make sure that there are excellent people in the

mission-oriented agencies. We have some great men, of course, in those agencies. We should keep them strong.

Mr. DADDARIO. Then your recommendation is that basic research be continued in the mission-oriented agencies, and that this not only creates new knowledge but also develops within each of the agencies a competency which it ought to have?

Dr. SEITZ. That is right. My memory goes back to the period 1938 and 1939 when we were making the first buildup in our armed strength. At that time the War Department, I guess it was called then, was very, very far removed from basic science. I would hate to see us go back to that period where there were very, very few distinguished scientists in the agencies.

Mr. DADDARIO. When you talk, Dr. Seitz, about supporting the National Science Foundation in a balanced and rational way, what do you mean by that? Are we doing it now, and what do future trends appear to be to you?

Dr. SEITZ. I think the largest concern I have personally, and I believe many of my colleagues in the Academy's advisory committee would feel the same way, relates to the support of what I call the independent scientist. There are in our country many scientists who carry on research in a modest way. I detect certain forces at work to keep the overall support for that group of scientists at a level at a time when the number is growing because of the expansion of educational programs. I hope we will keep what Dr. Kistiakowsky calls "little science" well funded. I don't think there are so many of these individual investigators that the expense is significant in our national budget. But there is a tendency for the very large programs to put pressure on that may cause us to cut back on the support of "little science." I think that would be a dangerous situation.

Mr. DADDARIO. Is this concern indicated by the advice the National Science Academy's committees gave to the National Science Foundation when it made its budget?

Dr. SEITZ. Yes, I think the proposed 1966 budget of the Science Foundation was very well balanced in this respect. It reflected opinions of many individuals, both in this respect and in respect to matters related, for example, to geographic direction, which is also of concern to us.

Mr. DADDARIO. You refer to the fact that the National Science Foundation does draw advice from a large part of the scientific community in developing its programs and budgets. Could you go into that in some detail? How does it work? What are the mechanics through which this advice generates itself?

Dr. SEITZ. Well, the Foundation, in addition to having its Science Board, which is representative in a broad way of both the scientific and the scientific administrative community, has various panels that are advisory to its own structure in various fields of science. I served for a number of years, for example, on the committee or panel in the field of mathematics, engineering, and physical sciences. It has advisory groups of that kind. Then, as I mentioned, it turns to the Academy committees. We have some 5,000 scientists and engineers that generate the reports that we prepare. It cuts very deeply, not

merely into the academic community but also the industrial community and governmental scientists. I think those are, perhaps, the main sources of advice, although there is, as you know, within the executive structure a great deal of flow, frequently, from PSAC to the Science Foundation or the Office of Science and Technology to the Foundation, because of the Federal Council within the Office of Science and Technology which reviews scientific matters. It is quite an extensive body.

Mr. DADDARIO. Dr. Seitz, you said that, prior to World War II, we had developed a respectable capacity for basic research, funded mainly through private and State sources. What is the danger of those sources shrinking as Federal participation gets larger? Are there any dangers, or is it growing in proper proportion to the Federal funds?

Dr. SEITZ. I think it is definitely growing in proportion to the Federal fund, and, remarkably enough, the Federal support has had a profound effect, for example, on alumni bodies. The average university president gets much more money from the alumni association than he did, for example, before the war. The State budgets are growing for higher education and correlated research somewhat in proportion to the Federal budgets. I think the Federal money has had a catalytic effect completely across the board.

Mr. DADDARIO. Rather than seeing a danger of Federal domination, you see the course of events as one of fairly good balance at least?

Dr. SEITZ. I would say there is excellent balance at present.

Mr. DADDARIO. Mr. Roush.

Mr. ROUSH. Dr. Seitz, I am very much interested in the small college or university. I have five of them in my district, and I serve on the board of trustees of one of these colleges. Three of the five colleges in my district have recently constructed new science facilities, and yet there is very little basic research taking place in these colleges and in these facilities. It has occurred to me that there are certain types of endeavor which could take place in a moderate facility such as we have in these schools, but the great difficulty we have is in paying a salary which is sufficient to attract a man who might be doing basic research into the small school. They tend to migrate to the larger universities where they may have a lesser position but still are paid more money. Have you given any thought to this, or would you care to comment on this, which is a problem to me?

Dr. SEITZ. I recognize the problem. I must admit that I don't see a simple solution to it, particularly in the fields of science. As science evolves, it inevitably requires more and more sophisticated equipment. As one probes deeper and deeper into nature, the equipment becomes more complex. It must be so. The string and sealing wax days are gone. The small colleges are at a disadvantage in procuring such equipment. In some cases, relationships can be established with the bigger universities and the staff, if they are in proximity, can use facilities in their spare time. I don't see any simple solution to it.

Mr. ROUSH. I would guess that there are probably 5,700 students in these 5 small schools. Out of those 5,700 people, I would imagine

there are several very bright young people who are interested in science, but maybe because of a church relationship or because they can't afford to go away to school, they are stuck in this small school, and this talent may be lost forever.

Dr. SEITZ. I note that a number of the colleges which once were regarded as 4-year schools are now adding graduate departments. I am thinking, for example, of Dartmouth and others. I have a feeling that somehow that must be the future for many of them, perhaps by joining together in a shared program, something like the Claremont group on the west coast, some specialization which allows the addition of graduate programs, graduate students and the acquisition of those things which you can have when you have graduate programs.

Mr. ROUSH. Thank you.

Mr. DADDARIO. Mr. Vivian, any further questions?

Mr. VIVIAN. No questions.

Mr. DADDARIO. Mr. Chairman?

Mr. MILLER. No, but I would like to say I am very happy to be here and to see Dr. Seitz. I appreciate the great contribution that he has made in his position, and the great assistance that he has been to this committee. I am always happy to see him.

Mr. DADDARIO. We are pleased to have you here, Mr. Chairman. I know you have come because Dr. Seitz and Dr. Waterman are our witnesses this morning.

Mr. YEAGER. Dr. Seitz, recently you had occasion at Purdue to discuss the project system in relation to the institutional grant. I wonder if you would care to comment on that to the committee, or give us the gist of that discussion? Is it in balance at the present time; is it a situation that can take care of itself; might it be improved, or any comments you might have in that area?

Dr. SEITZ. Let me hasten to say that some of my friends regard my points of view expressed at Purdue as somewhat controversial, that is, not everyone in the Academy agrees with me completely. On the other hand, there are those who do.

The project system has been a wonderful thing and I think we want to continue it. There will be instances in which an agency recognizes that an individual on an institution's staff is so distinguished that it will want to select him out and give him money directly. I didn't at Purdue advocate the abolition of such direct support. I believe, on the other hand, that if you have an entire institution which is distinguished it would, in my opinion, be wise for both the agency, for example, the Science Foundation, and the institution to agree that they will provide institutional support which the university will then distribute to its staff in relation to their needs, using the faculty and the administration as a team. I have seen that work. At the University of Illinois there is a research board which distributes certain money which comes to the university from the State and some of it in the form, of course, of institutional grants. The members of the board sit around the table and analyze the proposals from the faculty members. They do it wisely, amicably, and I think it can be done in many universities. What would result would be a certain economy in the process of decision. I think in addition it is wise for the university to learn to do that. I guess if

I were asked to make a recommendation, and I want to emphasize that this is a personal opinion, I would like to see about half of the money handled by institutional grants and perhaps half on the project system. But there are those who disagree with me.

Mr. DADDARIO. Dr. Seitz, I want to thank you for having appeared before us this morning and for the advice you have given us. I hope we might be able to send some questions to you to be answered for the record.[1]

Thank you very much.

Our next witness is Dr. Alan T. Waterman. We are pleased to have you here this morning, Dr. Waterman. The committee is privileged by your presence. We have over a long period of time on this committee looked to you for guidance and advice. The fact that you were the first Director of the National Science Foundation brought you into close proximity with this committee for many years.

STATEMENT OF DR. ALAN T. WATERMAN, FORMER DIRECTOR OF THE NATIONAL SCIENCE FOUNDATION

Dr. WATERMAN. It is a great pleasure to be here, Mr. Chairman, not only because the subject is one in which I am still extremely interested, both from the standpoint of science in general and also the NSF, but also to associate with you briefly again on affairs of mutual interest.

May I say that I have always appreciated the work of this committee, Mr. Miller, the overall chairman, and yourself in the intelligent approach you have always taken with respect to the activities of the Science Foundation. It has always been very valuable to us.

On this occasion your very thorough review seems to me a very timely thing. There are many questions floating around concerning what the country should do about research and technology, the sums of money that should be invested, and how much the Federal Government should participate. These are serious questions; they should be reviewed and understood. In fact, I think one of the most important things we can do about science today is to see that these matters are much better understood by the public generally and, of course, by the scientific community, industry, and government.

Since my printed testimony, Mr. Chairman, is on the long side, if it is agreeable with you, I will just give a synopsis of this, following the general outline but bringing up the topics somewhat differently.

Mr. DADDARIO. That will be fine, Dr. Waterman.

(Dr. Waterman's prepared statement appears at the conclusion of his remarks.)

Dr. WATERMAN. In the first place, I would like to endorse what I believe has been said by many others—and I think what your committee may also feel—that the National Science Foundation Act has served very well indeed. It is a tribute to the Congress in the first place that an act should have been devised of this character, breadth, and flexibility. In my opinion this is exactly the way that

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

science affairs should be handled in the Government, and it was a real step forward when the Federal Government decided upon this particular way of dealing with the subject.

In the National Science Foundation Act—I am not going to go into its details; you know the history, of course, very well—I should like to call attention to two points where there has been some misunderstanding and where I believe the solutions have been good.

In the first place, because of the breadth of the National Science Foundation Act, it was possible for the Foundation to make decisions with respect to its programs and policy from the very beginning, with the assistance, of course, of the administration and the Congress. One of the first things which we decided—all of us—was that the Science Foundation should not monopolize the support of basic research. This was an important step because at the time there was considerable pressure to do just that. This was settled by Executive Order 10521, in 1954, which was worked out by the Foundation with the Bureau of the Budget. Essentially this stated that basic research should be authorized and supported by Federal agencies concerned with research and development but that this basic research should be closely related to the practical mission of the agency. This policy has withstood the test of time very well, and, as Dr. Seitz has already testified, I believe it to be extremely important. No general outside agency such as the Foundation can do as much special research as, say, the Department of Defense, NASA, or the Atomic Energy Commission require.

This means that in its role the National Science Foundation should be aware of what basic research is going on in other agencies and complement that by its own program, and, of course, go into the fields which are far removed from the practical, so as to achieve a good comprehensive program for Federal support.

The second point about the act was one which stated that the National Science Foundation should evaluate the research programs of other Federal agencies. At the very beginning when I was asked if I would serve as Director I wanted that clarified, because I do not think it would be proper for an agency on the same level as other agencies to attempt to evaluate and supervise their programs. This leads to a division of authority. Practical agencies have reasons for doing basic research that would not be the Foundation's reasons, and I did not think, and still do not, that this kind of evaluation is a desirable thing for the NSF to attempt.

On the other hand, the interpretation which I put on this is I think valuable. Perhaps more could be done with it; that is, the Foundation should find out what is going on in other agencies in the support of basic research by fields of science—physics, chemistry, mathematics, biology, etc. Then if one puts together the agency programs in the field of physics, in the field of chemistry, and so on, one can by means of existing advisory committees and with the help of the National Academy, if desired, survey these and evaluate them as Federal programs in science. That is a very different matter from trying to criticize agency programs as such.

Now, obviously the Science Foundation cannot do this alone; it requires other agency cooperation. It already does, as you know, study the basic research support in other agencies, publishes the

amounts which are spent among them in the different fields of science, and has a planning and analytic office to study these matters. This is a very important thing to do. Accordingly the second point about the NSF responsibility is, then, that it should evaluate science programs and not agency programs. Agency programs should be evaluated at a higher level.

Of course, to bring this up to date, we now have for coordination the Federal Council for Science and Technology, as you know, and also the Office of Science and Technology, both at a higher level; they can go into the review and evaluation of the programs of other agencies as such.

The Foundation I know still carries on close associations with the other agencies in the fields of science, so that responsible science administrators know one another, compare notes and cooperate as Dr. Seitz has already said.

Mr. DADDARIO. Would there need to be a new mechanism added to the present process of evaluation so that it would be possible to get a complete picture of science?

Dr. WATERMAN. This is the kind of thing now which the Academy Committee, headed by Dr. Kistiakowsky, is actually doing. Their information about what agency programs in science comes largely from the National Science Foundation and from the agencies themselves where this needs further elaboration. When one is going to make a thorough review, this ought to be done by a top committee. But in the interim between such reviews my view is that the Foundation's staff in association with the staffs of other agencies can review what is going on in Federal support of science. By the same token, as came out in your discussions with Dr. Seitz, if anything useful should come out of the research programs of the Foundation, this close association will enable the interested agency to pick it up. This does not call for a new mechanism, but only closer attention to an existing one.

An important question right now, perhaps the most important of all, is the optimum magnitude of Federal support of science. In trying to answer this, one has to define clearly what one means by a scientific program. That is a familiar topic to you. It involves the distinction between basic research, and applied research and development. These are overlapping areas, but the distinction in principle is clear. For the record I would like to sum up the differences; they are about as follows. In basic research one gets the source material for applied research; one gets new ideas. One gains increased knowledge and understanding of man and the world he lives in. It is by means of basic research that the advanced training of scientists takes place. Thus it is a most important activity of the colleges and universities, which are the source of our trained scientists. Its motivation is different from that of applied research and development since in basic research one seeks merely to find out something which is new and original. It is a very strong one. This motivation for discovering something original means that there is a built-in mechanism for coordination in basic research. That is to say, if as a research scientist I try to discover something completely new in the field, say, of cosmic rays, how can I know whether what I am trying to do is original unless I know what others are doing? And

they are all in the same boat. Therefore, we must communicate in order to know whether what we are trying to do is original. This is a very strong means of coordination and prevention of unnecessary duplication in the case of basic research; one can count on it. This does not mean that overall coordination should not take place among agency programs, and the Federal Council for Science and Technology was established to deal with this. For another point basic research is essentially unpredictable since it lies in the unknown, and since it is remote from ordinary practical affairs, its scientific value must be judged by scientists themselves. All of this means that basic research for scientific progress is best handled by an agency which is devoted to that special purpose.

In the case of applied research and development, there are great differences. In the first place, there are practical objectives which are specific and these objectives can be evaluated. The purpose should be known, its priority, what the undertaking will cost, whether it is worth the cost, whether it is feasible, and whether if the development is successful it will actually achieve the objective which gave rise to it. This must be judged by a large number of experts, not merely scientists and engineers, and it becomes a very complex problem. Applied research and development are properly the responsibility of special mission agencies like Defense, the Atomic Energy Commission, and the National Institutes of Health.

Actually, a good basic research program, as I have often said, is really an investment, and one wants to make it as sound as possible. As in an investment some of the projects you would call "sure" things, where the return will not be large, but it will be there. There should be others where the possible return may be very large but they are greater risks. If such one comes through, however, it will pay off handsomely.

As you know, industries have come to count on basic research in their own research departments, and when they do, they take this statistical view, too. If I remember correctly, one technical firm, for example, counted regularly on 15 percent of the money spent in basic research coming through and enabling new products for the company. That was enough to more than pay the cost. So, the investment may be sure, but where precise returns are going to come, you do not know in advance.

Actually, if scientists were to specify a most satisfactory program in basic research, they would probably advocate support of all competent scientists in their respective fields, the criterion being competency. This is the best way to uncover new knowledge wherever it may lie, to add to our source material for possible use and to be sure that we overlook no bets.

How close do we come to this degree of support? In present practice, this depends on the availability of funds and whether the scientific community know where to go for support. By now they know pretty well where to go. An approximate figure for the entire group of Federal agencies would come not far, I think, from the Foundation's figure: about 50 percent of the number of applications receive support, but at the present time only roughly 25 percent of the total amount of money asked is available for obligation. This means that there is a high degree of selection, a principle which I

believe is wise. But the amounts of money which are awarded do not measure up to the amounts that were asked. This can be serious. When a proposal is cut which has been carefully and conscientiously worked out, it may cause severe damage to the project. Admittedly, there are some proposals that should be cut; this is part of normal administration. But at the present time my general criticism would be that in agency attempts to improve program coverage, grants and contracts for basic research fall too short of the funds requested. As you can see, if it becomes known that agencies make a regular practice of cutting project budgets, there is a great temptation for an applicant to put in a budget that is larger than he needs so that when it is cut he gets what he wants. That is not a sound policy.

There has been much said about the distribution of basic research and research support in general throughout the country. I know that you have made a special study of this, too, I simply wish to point out that the distribution of the National Science Foundation research grants corresponds quite closely with the distribution of active research scientists throughout the country. That seems to me to be a rather fair way of doing it. What I would especially like to point out is one which to me is a very satisfactory way of dealing with this subject. One should make quality the outstanding characteristic in the selection of basic research for support. This is largely a subjective judgment, and one does the best one can. When an agency evaluates a large collection of proposals, there will be a few of outstanding quality. Obviously these should be supported wherever they are. There will be a lot that are excellent and very good. These, too, should be supported wherever they happen to be. Now, as one comes down along the rating of quality, one reaches a level where one has to cut off for budget reasons. One will find there a large number of proposals, all of about the same scientific quality, from all sorts of research fields and types of institution, large and small, young investigators, senior ones, and from different regions of the country. There is the place that the agency can pick and choose. The Foundation's practice in the past has been to select at that quality cutoff level proposals favoring remote regions, young investigators, small institutions, and so forth. Now, there is the region where one can make adjustments without sacrificing quality standards. If this is sound procedure then on receiving more funds, the Foundation could readily make wider distribution of them and correct a general trend which has been often called into question. I would just mention briefly——

Mr. DADDARIO. When you say it is a trend which is called into question on occasion, do you mean that it is proper that more be done in this area?

Dr. WATERMAN. I believe so. I think this is the way to do it. I don't think it should be done with any sacrifice of quality.

Of course, one has to realize that the agencies with practical missions do not have this objective. It is not really their business. They must get research results which are going to help them in their missions. So one finds the large agencies, generally placing their research where the highest competence lies so they can get a return for their money just as industry would do. The result is they don't

distribute their funds so widely, and I don't think they should. The Foundation can do it.

The other point I want to make in this connection is that I believe the NSF should have a larger proportion of Federal basic research funds for disbursement to academic institutions, to encourage research training and breadth of research support. I believe that according to the latest complete data (1963) NSF provides less than 30 percent of the Federal basic research support to academic institutions. I believe this should be higher. It would improve the distribution I spoke about; it would also increase the participation and leadership of the NSF in basic research councils within the Government itself. I think that here the Foundation could be of greater help to the Office of Science and Technology, in ways that Dr. Seitz has suggested.

Mr. DADDARIO. How high would you go when you say you should have a larger proportion?

Dr. WATERMAN. This shouldn't be done too quickly. One doesn't want to interfere with the programs that are going well in other agencies, and the Foundation's participation has grown. I should think the Foundation ought to come to at least 50 percent of the Federal support in basic research to academic institutions.

There is another point. In my opinion one has to be careful in supporting basic research that it all does not go into fields which are estimated to be of practical importance. History is very clear on this. Some of the capital discoveries have come in fields that have been neglected. In trying to anticipate the fields in which basic research is going to be practically important, one should not ignore the others. If you look at the overall program for basic research you will find that about 80 percent of the support is provided by agencies with practical missions, which by accepted policy means in fields where they expect results beneficial to them. That leaves only 20 percent for the support of free research—primarily in the interest of science. I think that is too small. This situation too, could be improved if the Foundation had more funds.

I have talked much of budgets, but you will note that the points mentioned are all based on policy principles. I should like now to call attention to the unique character of the National Science Board. It has helped the Foundation greatly in policy determination, in passing on actions, and in furnishing guidance. Since it has on it not only research experts but academic presidents, leaders of industry and men of affairs, it is a unique body in dealing with many of these policy matters. I believe more use could be made of it in the councils of the Government.

Next, I want to mention in passing that the National Science Foundation should continue to have close association with the National Academy of Sciences, with the American Association for the Advancement of Science and other scientific societies. I believe the National Science Foundation should be the colleague in the Federal Government of those scientific agencies. It can work with them on a highly cooperative basis, as for example, in international science programs or in special areas, as Dr. Seitz has already testified in its relations with the National Academy of Sciences.

One point I would like to stress—in the support of basic research, especially in academic institutions, continuity is a very important consideration. It is most disturbing to a university continually to have to jump from one research project to another because of a change in support or to call off scientists from doing one thing to take up something else. These plans have to be made slowly and carefully at universities, and they badly need assurance of stability. Thus continuity of support is a very important matter to them, and I think in this the Science Foundation should be in the best position to assist.

Another important matter is the following. At present the budget process calls for about a 2-year interval before the money is available. That means an agency can only start obligating a particular appropriation after a 2-year interval since its plans were made. As I have said, basic research is unpredictable. Suppose shortly after an agency gets its appropriation a capital discovery is made in basic research, or more than one, as may happen. Immediately the thing to do is to pay special attention to that field, to see that it is cultivated and, if there are any possibilities of exploitation, to let these go forward. But the agency budget planning was made 2 years ago; there is no money for contingencies like this. If some way can be found to provide a contingency fund for such emergencies, this would be a great national gain. I do not know how this can best be done, but I regard it as a very important matter, indeed.

Finally, I should mention the subject of international cooperation in research. In the particular case of very large and expensive installations or programs, we are reaching the point where these are going to be very troublesome in the Federal budget. They are very large; they may be very important. If we don't do them, then we fall behind in world competition. In the case of high energy particle accelerators, for example, if the nuclear physicists say that their progress in the analysis and the understanding of the atomic nucleus can only be advanced by building a new high energy particle accelerator, then what do we do? If we do not do this, we drop back in that field in world science. If we choose to go into it, one good way to economize is to do this with the cooperation of other nations, if this can be managed. On the European scene the organization known as CERN in Geneva is doing a magnificent job in this area, nuclear physics, in a concerted effort with other countries. We have done the same thing with other countries with the IGY and other programs. If space exploration, where the costs are enormously high, could be managed by friendly cooperation among interested nations, it would decrease the cost to any one of them, it would be an additional way in which we could get closer and friendlier association with them, and it would add the world's experts to this difficult accomplishment instead of just one nation's.

Finally, I believe, Mr. Chairman, that above all we must realize and appreciate the importance of what is coming up in research and development in improving our environment, in fact, in creating new environments, in exploring space, in exploring the depths of the oceans and the interior of the earth, in the study of life on earth and what can be done about our natural surroundings. We are making very rapid progress in all of them. It seems to me to be of the greatest importance

in the national interest to further the support of basic research on all these frontiers, and the training of scientists and engineers to do it. I believe that the NSF is the proper agency to take the lead in these matters.

Thank you very much.

(Dr. Waterman's prepared statement follows:)

PREPARED STATEMENT OF DR. ALAN T. WATERMAN, FORMER DIRECTOR OF THE NATIONAL SCIENCE FOUNDATION

Mr. Chairman and gentlemen, I am happy to have this opportunity to appear before you in your review of the policies and programs of the NSF and am very pleased at thus briefly renewing our long and friendly association. As an alumnus of that organization, I have a special interest in the subject. Perhaps I should warn you: Alumni of most organizations are apt to be conservative and resistant to change. However I do not think that applies so much to the former head of an organization; his mind is apt to dwell on situations where his efforts might have been more effective.

Let me say at the outset that I am most grateful for the intelligent interest which I feel the Committee on Science and Astronautics has always taken with respect to the NSF. The reviews of our programs which your committee held were always stimulating and valuable to us.

I shall not take time to go over the history of growth of the NSF and its present activities. This is well known to you and is provided in factual setting and detail by the very complete summary furnished by the report of the Science Policy Research Division of the Library of Congress.

Suffice it to say that by its passage of the National Science Foundation Act in 1950 the Congress went on record as showing its understanding and appreciation of the future role of science in our country. There was special significance in the manner in which this was to be organized and administered—by an independent agency devoted to the encouragement and support of basic research and education in the sciences, together with the development of national policy related thereto.

This action was a far-reaching policy decision and one of great wisdom. For it properly set apart the sponsorship and growth of science from research and development activities directed toward the achievement of practical national goals such as defense, health, atomic energy, space exploration, etc. It also recognized the intrinsic value of science and science education as a national goal.

At the time of its founding there were many who felt that all basic research should be supported by the new Foundation, or in any event that the overall Federal basic research effort should be supervised or directed by the National Science Foundation. Concerning these two propositions: The former was settled, quite properly in my opinion, by Executive Order 10521, in 1954, for which the staff work was done jointly by the National Science Foundation and the Bureau of the Budget. This stated that every agency involved in research and development should have authority and funds to conduct and support basic research in fields closely related to its mission. The reason is simple: A Federal agency with a practical mission, should engage in basic research which provides insight into its applied research and development problems and its future progress and which thus it can defend in its budget. As our highly successful technical industries have amply proved, it is important for an agency to participate actively in basic research and thus get this background at first hand, not solely through outside sources. Furthermore a plurality of sources of support avoids the hazards of monopoly.

The idea for National Science Foundation supervision of basic research programs of other Federal agencies, stems from a natural desire to achieve coordination and elimination of duplication among the 40-odd Federal agencies engaged in research and development. This is a more complex matter. In the first place the executive branch is not organized in such a way that one agency can or should evaluate and report on the effectiveness of the programs of another. The mission of a given agency should be its own responsibility, for which it has had abundant experience and for which it should be held accountable, to the President and to Congress—not to a sister agency.

With respect to duplication in basic research, however, there is a far more fundamental and effective solution than the appointment of a coordinating body. When I say "duplication" of course I mean undesirable duplication, since some duplication is commonly required in basic research in order to check the accuracy of the result of a single research investigation.

Now basic research has a built-in coordination which prevents undue duplication. The advancement of a basic research scientist in his field depends upon the originality and the soundness of his work. His aim is to make a unique contribution to knowledge in his field—something no one has ever done. It is clear then that he must know what has already been done and what others are doing in order to be reasonably certain his work is original. Since his colleagues in his field are all in the same situation they must and do communicate with one another as to their current research. For a basic research scientist to repeat unnecessarily the work of another is to commit professional suicide. This provides the strongest of motivations for coordination; it constitutes the built-in mechanism I mentioned.

While this completely minimizes the risk of unnecessary duplication in basic research, nevertheless the need for coordination among Federal basic research programs is of course desirable. Curiously, the National Science Foundation Act does not mention, except by implication, a Foundation responsibility for coordination of basic research among the Federal agencies involved. It does, however, stipulate that the Foundation evaluate the research programs of other agencies. On this point you may be interested to know that when I was approached regarding the position as Director of the NSF I pointed out that one interpretation of this provision was not feasible nor proper; namely, NSF review and evaluation of the research and development programs of other Federal agencies. In the first place, the competence of the NSF would lie in basic research and not in development. More importantly it was improper for one Federal agency to attempt to evaluate and in that sense supervise the work of sister agencies. My interpretation of how I would carry out this responsibility was accepted. It was as follows: The NSF should take steps to secure information by fields of science from other Federal agencies regarding their support of basic research. Thus the NSF should determine the basic research activities throughout the Government in the fields of physics, mathematics, etc. In this way the Foundation could plan its own research programs to supplement and round out the work carried out by other agencies. Also, with the help of its divisional and other advisory committees, it would then be in a position to evaluate the basic research performed by the Federal Government in each of these scientific disciplines. Accordingly the Foundation began at an early date to collect data concerning the basic research of other agencies. This system has the advantage of bringing together the science administrators of other agencies in their common fields of interest.

One of the fundamental questions of today concerns the optimum magnitude of the overall basic research effort. As a matter of national policy, what should be the present and future levels of support for basic research What proportion of that support should be borne by the Federal Government? By the NSF? This is a subject which, as you know, has been undertaken for the Federal Government by the National Academy of Sciences in its Committee on Science and Public Policy.

The first point to be settled is to know what we mean when we say "basic research." For the record—this explanation being superfluous for this committee—it cannot be too strongly emphasized that basic research must be carefully distinguished from technology. For some reason science is associated in the public mind with military and other highly visible items, such as weapons, aircraft, satellites, refrigerators, TV sets, deodorants, insect killers, and mechanical carving knives. These are of course the end items of a series of steps—applied research to demonstrate the feasibility (in principle), development to engineer and test a practical device for production, and finally production and distribution. One commonly hears such statements as: the country is spending $20 billion on research; the Federal Government is this year proposing to appropriate $15 billion for science. These are serious misstatements. Sums of this magnitude represent appropriations for research and development of which the funds designated for basic research amount only to about 10 percent. If one is worried about the Federal budgets for R. & D., then the place to make any significant saving is obviously where the heavy costs occur—in development

where 70 percent of the expense lies, and its related applied research which adds another 20 percent.

The role of basic research is simply to furnish the source material and the initial ideas for applied research and development. At the same time, in its natural habitat, the colleges and universities, it provides for the advanced training of scientists and engineers, to be available for careers in industry, government, and the academic institutions themselves.

Applied research and development are characterized by having practical objectives, usually quite specific. Their evaluation must include evaluation of the objective, its priority, and its feasibility.

On the other hand: (*a*) the findings of basic research are in general unpredictable, since they lie in the unknown; (*b*) a basic research finding commonly carries with it no connotation of immediate feasibility for practical application.

Thus, Einstein's capital discovery half a century ago of his famous equation, $e=mc^2$ contained the theoretical possibility of the conversion of mass into energy. When asked whether this discovery might some day be put to use he replied that he saw no possibility of this. The key to this hope of feasibility finally appeared with the discovery of nuclear fission in 1937, again in basic research. But practical exploitation came only during World War II by a most elaborate and costly national effort in applied research and development where, as a matter of fact, the issue of practical feasibility was long in doubt.

But there are other and equally important distinctions between basic research and technology. First there is motivation. Generally speaking the basic researcher is out to secure new knowledge and not something directly useful. Thus his search is broader and more likely to result in some addition to our fund of knowledge, always useful to other scientists but not immediately or necessarily to technology. Since his standing and his future in his profession depend primarily upon the originality (and soundness) of his finding, this motivation is very strong.

In examining a basic research program no one outside the field is justified in trying to place a value upon a particular research project by its field or by its title. Such judgments have validity only when made by experts in the field in question; they depend upon the current status of the field and especially upon the competence of the researcher. Besides, as is well known, some of the most surprising and far-reaching discoveries have occurred in little known and unexpected territory. Consequently the review and evaluation of basic research must be conducted by the scientists themselves.

Actually a first-class basic research program is comprehensive in scope and has the characteristics of an investment—some "sure things" of probable small but certain return, and others of high promise but problematical as to accomplishment. Another unique characteristic of basic research bears mentioning: a confirmed negative result has value, in preventing further time and effort on the subject.

Now contrast this philosophy with that of applied research and development. Here one starts with a reasonably clear objective. This immediately raises a number of questions: What useful purpose is the proposed undertaking expected to serve? How important is this objective and to whom? How much will the effort cost in dollars and manpower? Is it worth this investment? Is the proposed plan feasible in execution? If successful, will it actually achieve the objective intended? This indicates clearly that the evaluation of a proposal for an R. & D. undertaking brings in many considerations other than scientific, and consequently the exercise of judgments among many other than scientists, such as administrators, management, manpower and budget specialists, engineers, analysts, technologists, and individuals experienced and expert in industry, business, and public affairs.

This whole matter may be likened to the opening up of a new territory. The comprehensive exploration of the territory corresponds to basic research, the search for mineral or other resources corresponds to applied research, and the study of how these resources may be exploited corresponds to development.

In sum, therefore, basic research programs lie in a category by themselves. The soundness and value of a basic research program can only be evaluated by scientists with high competence and experience in their fields.

What conclusions may be drawn from this? First, a national program for the advancement of science should be the primary responsibility of an independent agency with that explicit mission—progress in science. Such an agency is the NSF. Only in this way can a fully developed and sound basic research pro-

gram be developed and maintained, with the desirable degree of continuity and coverage. In the comprehensive program sponsored by such an agency, account should obviously be taken of the basic research programs conducted and supported by other agencies. But the overall program also should be watched. For example, the basic research program of an agency with a practical mission may overfinance a particular field in the effort to reach an important objective, or several agencies may unwittingly plan to stress research in the same field, thus putting a severe strain upon available scientific manpower and facilities therein and detracting from support needed in other areas of science.

From the standpoint of the progress of science alone, for the desirable level of support of basic research, consensus among scientists would advocate support for all competent scientists in the research they judge to be most promising. The line would be drawn at the criterion of competence—admittedly a subjective one and difficult to judge. In practice, the most feasible way to solve this problem is to provide a level of support which will require competition among applicants for support. Then, provided the availability of funds is well known to prospective applicants, the program should be selective of the country's best research talent. Decisions as to selection must then be made with the advice of research experts. This, of course, is the so-called project system. From all accounts it has worked well and should be maintained. This is a recommendation of the Committee on Science and Public Policy. Notice that this system does not, of itself, introduce priorities as to scientific field—the essential criteria being scientific promise of the research and the competence of the investigator(s). This is consistent with the point of view of pure science—all fields are important; capital discoveries may be made in any of them.

The NSF has had considerable experience with the project system, developed according to these principles. It is generally followed by most R. & D. Federal agencies, with one important difference—among agencies with practical missions, in the selection of the field or subfield supported the relevance of the basic research to the agency mission is an important factor, as is the possibility of valuable applied research opening up as a consequence of the basic research findings.

How closely does the present Federal support of basic research come to complete coverage? On analysis one finds the following. Somewhat less than half of the applicants for basic research proposals are successful in securing funds in the mathematical, physical, engineering, and social sciences and more than half in the life sciences. In the NSF the figure has been close to 50 percent. On the other hand the proportion of funds awarded to funds requested is in the neighborhood of only 25 percent for the physical sciences group above; it is considerably higher for the life sciences, reflecting the greater availability of research funds in the latter area.

While some of this pruning of individual project funds is undoubtedly justified it must also be admitted that as a policy it can do much harm. Many a scientific project is conscientiously budgeted and is severely handicapped by curtailment of funds. Besides, once this practice becomes general, applicants may quite naturally try to protect their requirements by sending in inflated budgets. And one can hardly blame an agency for attempting to cover all worthy requests. At the moment in most scientific fields progress in research and in the training of young scientists is judged to be in serious trouble on this point—adequate financing—especially in the physical sciences.

An increasing complication in attempting to reach an optimum level of support while dealing fairly with all fields of research is the large and rapidly rising cost of certain research areas, usually due to the necessity for large or elaborate installations—notably, high energy particle accelerators, radio telescopes, oceanographic research vessels, and scientific satellites and probes for the exploration of outer space. What makes matters worse is that the maintenance of such installations is correspondingly high. Furthermore, the large amounts required for these purposes involve competition with other national priorities outside of science or drastic curtailment of general research funds.

This difficulty is probably best met by separating out from the general research budget all capital items of this costly nature so that consideration of their financing may be met more directly than by their inclusion in the regular research programs. In the view of the undersigned, a most inviting prospect for reducing this kind of strain on the national budget is to encourage the scientists in the field in question to work out a plan for international cooperation as the European scientists have done in the case of CERN for costly high energy

physics installations. If such cooperation could be secured for research in space exploration by the nations with interest and competence therein, enormous savings in money and manpower would be made by the participating countries, as well as providing a most effective basis for improving international relations.

One of the major questions engaging the attention of the Congress and the country at large is the distribution of research support among the various regions of the country, their industries and their institutions of higher education.

Much has been said about the inequity in distribution of Federal research funds going to colleges and universities. Thus with a total of some 2,100 colleges and universities in the United States practically all funds for research go to less than 400. This is highly misleading. Let me remind you that these 2,100 include a great many special institutions (30 percent) not commonly associated with the usual term higher education. Only about 55 percent of this total, or about 1,150, grant degrees in mathematics, science, or engineering, and of this 1,150 somewhat less than 400 report research activities in science. Furthermore, these 400 institutions include over 99 percent of the country's scientists in academic institutions. Thus, on going beyond this group of 400, one finds only about 1 percent of our academic scientists employed in the remaining 750 institutions granting science degrees; practically all of these are engaged only in teaching, in accordance with the policies of their institutions. Accordingly, the general distribution of funds among academic institutions appears to be reasonable. In this connection one must remember that mission-related agencies must regard as their primary justification for the support of basic research the value of the prospective results and the relevance of the latter to their practical missions. It is not their responsibility to make equable distribution of research funds throughout the country and among large and small institutions. Considerable improvement of this situation would be made by allocating a greater proportion of Federal funds for research to the NSF which does include such a responsibility.

I understand that at present the NSF provides basic research support to some 338 colleges and universities. If one includes educational support which is related to research, the NSF provides support to 850 academic institutions.

In my judgment this is a reasonably healthy situation, providing as it does for a fair degree of competition in order to secure Federal support, whether for research or for special education and training purposes.

As a matter of fact, the NSF has disposed of its requests for basic research roughly as follows: After evaluation incoming proposals can be arranged in approximate order of quality. Those of the highest quality should receive grants regardless of location or type of institution, simply in the interest of progress in science. The current appropriation of the agency necessarily establishes a cutoff point, determined by quality considerations. At this quality level, however, there will be found a large number and variety of proposals from all sections of the country and from all types of institution. It is therefore possible at this level to exercise preferences in favor of small rather than large institutions, young and relatively inexperienced investigators, and to make more equable distribution among different regions. The resulting distribution may then be analyzed, as the NSF has repeatedly done. In general, the results have always indicated that the distribution of support corresponds closely with the active research population of the region. That is to say that the grants are distributed about uniformly among the competent research scientists wherever they are.

If this principle is followed in awarding basic research grants, then it is clear that an increase in the basic research appropriation for the agency would improve the distribution by permitting more opportunities for selective encouragement of small institutions and have-not regions, while still adhering to overall quality standards, and without sacrificing competent research at the larger research institutions.

Considerable thought and discussion have been given in recent years to the distribution of support to science among the universities of the country. This has arisen from the observation that so much of the total basic research support goes to so few universities. A wider distribution would relieve the strain on this latter group and at the same time provide incentive and opportunity for other universities to join the group of leading research institutions. Such a provision was strongly advocated in a report by the President's Science Advisory Committee entitled "Scientific Progress, the Universities and the Federal Government" (1960), which specifically recommended that the number of leading research universities be approximately doubled.

As you know, the NSF has taken steps recently to improve this situation by the introduction of its science developmental program. This is aimed not only at increasing the number of universities just mentioned, but also at improving the scientific capabilities of other classes of academic institutions both large and small. This is a most worthy and timely cause. It must be acknowledged however that to do this selectively, which is the logical and most efficient way to begin, is a highly complex and difficult undertaking. The allocation in the 1966 budget request for this purpose is only a small beginning. However it should provide the NSF with the requisite experience, and evidence as to the most feasible approach. It should be abundantly clear that high standards of quality and promise should be maintained and that again the element of competition be present.

GENERAL CONCLUSIONS

Both from my own experience and from following the excellent progress of my friend and successor Dr. Haworth (assisted by my many other warm friends and associates among the staff), I have no hesitation in stating that the National Science Foundation Act has been an intelligent, satisfactory and forward-looking ing document. It has served the Foundation well and should continue to do so. In general it has provided the Foundation not only with authority to carry out programs clearly foreseen at the time of its issuance but also to initiate timely additional ones and especially to introduce these experimentally so that their character and growth may be more clearly determined from experience. In fact I find it hard to resist the temptation to remark that there is little about the Foundation's programs that more money will not fix.

In the National Science Board the Foundation has a notable asset and I can speak most warmly and enthusiastically about its helpful actions, advice, and guidance. It is in fact a unique body and one whose services I have always felt could well be authoritatively used on matters of national policy in science and education going beyond the Foundation's own programs—in Government-university relationships for example.

You have asked me to make specific suggestions or recommendations. I have some hesitation in doing so since the soundest recommendations are bound to come from those with active responsibility, namely, the Director, backed by the National Science Board. Besides, I do not wish to give the impression by my remarks that they are in any sense critical of Dr. Haworth's administration, for which I have nothing but praise.

I do have in mind certain points to raise as suggestions for consideration. They are as follows:

(1) Steps should be taken to materially increase the budget of the NSF in order that greater advantage may be taken of the proved assets in its programs. Specifically, the allocation for research support should be markedly increased in order that the Foundation may provide a greater proportion of Federal support in basic research to academic institutions.

The present figure, less than 30 percent I believe, is too low to enable the NSF to complement the basic research support by other agencies and insure that Federal support maintains a proper balance among the various sciences.

Furthermore, as I have explained, additional support in this category will bring about a more effective regional coverage, among large and small institutions, and in the educational advantages that such extension will provide.

Such a provision would also serve to strengthen the position of the NSF with respect to basic research policy within the Federal Government, a role for which it now has extensive experience and competence. This strengthening of its role should be of valuable assistance to the Office of Science and Technology in the latter's consideration of this and broader issues involving science.

As I have stated elsewhere,[1] in my opinion the proportion of Federal support of "mission-related" basic research is too high—about 80 percent. My reasons are as follows. One of the strengths of a country such as ours is the encouragement of free and independent inquiry. Completely free research extends the opportunities for new and valuable findings. Cultivation of the broadest possible base for research benefits interdisciplinary research programs; it prepares the scientific community for the broad knowledge and flexibility which are needed in a rapidly changing world. Finally, such a move would prevent overemphasis upon too few selected scientific fields, under programmatic and budgetary pressures.

[1] "The Changing Environment of Science"; Science, Jan. 1, 1965.

In this connection it should be remembered that the NSF is in the most effective position to encourage the intimate relationship that should exist between research and training at academic institutions.

As a practical administrative matter the NSF increase in workload to deal with an increased appropriation for this purpose would be relatively slight. The chief staff workload falls upon the scientist-administrators in the review and evaluation of proposals received. Thus, the workload is determined largely by the number of proposals received and not by the number of grants actually made.

(2) In the interest of improved communication and planning within each of the scientific disciplines and the potential utility of their findings the NSF should continue to develop the programs of its Office of Scientific Information Service, and also to exercise leadership in overall consideration of basic research subject matter areas. This may often involve or generate national research programs in which the Federal agencies may cooperate. Such cooperative undertakings should of course come under the cognizance of the Federal Council for Science and Technology.

(3) Increased use of the National Science Board as a distinguished and unique policymaking body in the area of research and education, with special reference to Government-university relationships in support of science.

(4) Continuation, at an increased level, of the program in support of education and training in science and engineering. This is a highly critical area for our future in science and technology. These programs have had marked success, and the NSF has established close and cordial relations with the scientific and educational community, by whom the programs have been enthusiastically acclaimed. By no means should this momentum be lost. It goes without saying that in this process there should be close cooperative relations with the Office of Education. The latter will be fully occupied with similar programs in fields other than science, and with overall improvement along general educational lines, especially in cooperation with the States.

(5) As on many occasions already, the NSF should be regarded as the logical colleague in the Federal Government of the National Academy of Sciences-National Research Council, the American Association for the Advancement of Science, and other scientific societies, in programs of mutual interest.

(6) One of the most serious matters in provision for basic research is to provide for (a) continuity of support and (b) contingency funds so as to take prompt action to followup a new and highly significant finding.

> (*a*) Lack of stability and continuity in research activity at academic institutions interferes critically with the effectiveness of their research programs, with the training of graduate students, and with the efficiency of their departmental and administrative operations.
>
> (*b*) A new research finding of high significance and promise calls for immediate research in verification and consolidation of its results and prompt extension of research activity to exploit the new discovery. At this stage there may open up an opportunity for applied research to investigate any practical benefits that may accrue.

During the 2-year interval required for the budgetary process, there is great likelihood that basic research findings may be made which demand this urgent followup. It then becomes highly urgent that funds be immediately available for this purpose, so as not to draw upon funds needed and morally committed to on-going programs of high quality and stability. I do not know the most expeditious way of providing such contingency funds but I can strongly vouch for their need and the strong backing of the scientific and academic community in so doing.

(7) The opportunities for cooperation in science programs with other nations is attractive, timely, and impressive. In so doing we may establish cordial and mutually beneficial relations in an atmosphere relatively free from troublesome political problems. For this we have a number of excellent precedents.

Besides the accomplishments of science and technology are going to become of greater and greater significance in the affairs of mankind. To make sound progress in such developments and to deal with them effectively will require the friendly collaboration of all. In such enterprises the NSF can play a leading Federal part, in cooperation with the State Department on the diplomatic and official side, and the National Academy of Sciences on the side of purely scientific relationships abroad, such as with the International Council of Scientific Unions and foreign academies of science.

In consideration of this and other problems in support of science and science education, one is inevitably led back to confront what is undoubtedly the most fundamental question of all; namely, consideration of our national goals.

Admittedly, progress in science is essential to the well-being of a nation in the world of today. In what sense is this true? For national defense, for health, for industrial and economic strength, for consumer benefits, improved standard of living and for cultural purposes? All of these surely, but is the goal only to achieve an adequate, acceptable standard in all of them? Unfortunately absolute standards in these categories cannot be accepted. We live in a competitive world; consequently standards have to be relative. Where or how are we going to stop in consumer benefits and improving the standard of living? What constitutes an adequate program in national defense or space exploration? Or an adequate science program? Among the community of nations and with our present responsibilities our answer must surely be that to compete successfully we must be in the forefront of research in science, in all fields. Why all fields? Simply because there is no predicting where the most significant progress may occur, and also because of the increasingly important interrelationships among the sciences—the so-called interdisciplinary approach. Now how should we deal with very expensive items? Should they be excluded solely because of their cost? In certain areas we cannot do that and maintain our position among the leaders in the field. If we adopt this negative position, then we are bound to experience periodic and rude awakenings, as we have already encountered on several occasions, with the ensuing overcostly crash programs and general consternation.

It goes without saying that such decisions are extremely difficult to make and that fiscal items of this magnitude must come into competition for funding with other programs lying outside or on the border of science. But in considering such items we should always bear in mind their feasibility. For example the record shows that we know how to build successful high energy particle accelerators which have lived up to the specifications of their designers. By the same token it may fairly be said by way of justification of man's trip to the moon that we know how to do it; we have far more assurance of succeeding in that than we have of preventing crime, of eliminating pollution or traffic accidents, or eliminating poverty, important as these problems are.

Finally, we must realize that world competition in science and technology is going to be a most serious matter. To meet this our best insurance is research, basic research to give the background and the leads for the future, and applied research to identify the feasibilities for development. In order to make optimum progress in science and at the same time provide for the requisite scientific and technical manpower we must concentrate attention upon supporting the colleges and universities that produce this trained manpower.

We must realize that science will continue to bring to light research and development programs of greater and greater import for mankind. These will be impressive but some will also be very expensive. If we fail to undertake them we jeopardize our position among the progressive nations of the world and our opportunities for leadership. If we do undertake them we shall then have the choice of financing and manning the effort alone, or enlisting the cooperation of other countries. In view of the global character of some of these ventures, their extreme cost, and possible social implications, we should give increasingly serious consideration to this latter alternative—taking the lead for collaboration among nations.

If we are to be able to do justice to the impressive potentialities of science and technology, one of our chief concerns must be a better public understanding of science and technology. Hopefully, in time, we shall be able to include science in the education of every child, but for the present it is important to try to give all citizens a clearer idea of the subject. Unless this general type of public understanding is developed, the country will not be prepared to deal intelligently or effectively with the major discoveries in science that are certain to occur.

Many of these will inevitably lead to issues involving technology that society will have to decide. Here the questions cannot be left to the scientists and engineers alone; their role is primarily to point out the scope and nature of a new field, its possibilities and limitations. We have already seen social questions of this sort arise. But it is certain that science will open up possibilities for development of an even more critical nature, in such sensitive fields as biology, for example. Imagine the social consequences of a discovery that would

prolong human life to double its present span, or one that would predetermine the sex or other characteristics of a child. We do not know at the moment what discoveries of such critical magnitude will emerge, but we can be confident that discoveries of this degree of importance will ultimately occur. When that time comes, it is clearly of the greatest importance that all educated citizens be able to take an intelligent position on these issues.

One cannot conclude a discussion of the far-reaching sweep of scientific progress and its consequences without stressing the involvement of international relations. An increasing number of scientific problems are and will be global in nature and can be intelligently and effectively administered only by international cooperation.

For all these reasons it is of the greatest importance to move in the direction of increasing international cooperation in science, and where feasible, in development and technology.

Along with the present breadth, complexity, and inherent power of science and technology we are finding ways of overcoming many of the environmental hazards that confront us and indeed to create for ourselves entirely new environments. However, we are also learning that such applications of science may introduce new problems and new hazards to overcome.

It is especially important to realize that we are now beginning to take large and unprecedented steps in the exploration of our surroundings—by research into outer space, into the ocean depths and into the interior of the earth. We are making notable progress in ecological studies of our immediate environment and the further development and conservation of natural resources. In the biosciences we are coming ever closer to a knowledge of the origin and development of life. And we are making significant progress among the behavioral and social sciences.

The potentialities of these undertakings are most impressive. They are of a character to warrant full attention and support by the Federal Government, both in national and international planning.

In the attainment of the science components of these goals, I firmly believe that the National Science Foundation occupies a unique position in our Government—one that should be maintained and enhanced.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have several questions.

You indicated earlier that you attempted geographic distributions, or had done so in the past. Some comments were made in this regard by the present Director several days ago as to those projects which came toward the bottom of the pile and which are of nominally equal quality. I personally think this is a wise procedure. I also think that the comments made that the top proposals should be approved regardless of where the applicant happens to be is also equally wise. I am curious to know, however, what is the percentage of funds which can be adjusted to some extent on a geographical basis.

Dr. WATERMAN. I don't recall the figures which were of course only approximate. I believe the Foundation may be able to give them to you. The general type of curve shows a relatively small number of top quality proposals with the number increasing as one goes down in the quality scale, together with an increase in variety and source of proposals. Therefore, with a severely limited budget the coverage is limited; an increased budget increases the coverage and broadens the distribution.

Mr. VIVIAN. There is a system, I believe, utilized within NSF for rating. If I were to look at the last, say, 20 percent on the rating curve, I should find a different geographic distribution for those say, on the top 50 percent of the rating curve?

Dr. WATERMAN. Yes.

Mr. VIVIAN. I see Dr. Haworth in the audience. I would appreciate if I could get that information. I presume that is available.

Dr. HAWORTH. Not quite as specifically as you indicate. One can give a rough idea. The proposals aren't all assembled at the same time and rated with numerical ratings and so forth.

Mr. VIVIAN. I recognize that. I undoubtedly asked the question in a context which is hard to answer. I am sure there is some approximate context.

Dr. HAWORTH. We will do the best we can.

(The information follows:)

NATIONAL SCIENCE FOUNDATION,
OFFICE OF THE DIRECTOR,
Washington, D.C. August 16, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, House of Representatives, Washington, D.C.

DEAR MR. DADDARIO: During Dr. Waterman's testimony before your Subcommittee on Science Research and Development on June 30, 1965 (transcript, p. 290), I stated that the Foundation would furnish information requested by Representative Vivian on certain aspects of the geographical distribution of those proposals which were accepted for granting by the National Science Foundation. Specifically, Representative Vivian was interested in the geographical distribution of the top 50 percent and the lower 20 percent of the grants on the basis of quality rating.

A study has been completed of the regional distribution of the research grants made during fiscal year 1964 which included the upper 45 percent of the grants and the lower 19 percent of the grants, by number. These groups respectively accounted for approximately 52 and 13 percent of the funds. (Our rating system assigns projects into quality groups. The statistics were such that breaks between groups occurred at the points used.)

In attached table the region are listed in the order of decreasing NSF basic research support per Ph. D. I should also point out that the data determined were for only 1 year and that averages over several years might be somewhat different.

I shall be pleased to attempt to provide further information on this subject, if you desire.

Sincerely yours,

LELAND J. HAWORTH, *Director.*

Region	States	Regional fraction of total dollar amount contained in upper 45 percent of grants (by number)	Regional fraction of total dollar amount contained in lowest 19 percent (by number)	Percent of dollars in lowest 19 percent; percent of dollars in upper 45 percent
Pacific	Washington, Oregon, California, Hawaii, Alaska.	22.4	21.0	0.93
Mountain	Montana, Idaho, Wyoming, Nevada, Utah, Colorado, Arizona, New Mexico.	3.4	5.6	1.64

East South Central	Kentucky, Tennessee, Alabama, Mississippi.	.4	3.7	9.25
Total		100.0	100.0	

Dr. WATERMAN. Of course, this is a statistical matter. One finds plenty of instances in small colleges where a grant is given to an individual because of the high quality of his proposal. I have talked to many small college presidents about this. Many feel that one of the best things that can happen to their institution is to have one of their faculty get a research grant.

Mr. VIVIAN. I also might comment that while sometimes the phrase "Midwest" is used around here, I am also aware that in other portions of the country which are labeled as being high on the scale of those receiving research grants very often some of the smaller institutions in those areas are perhaps as undernurtured as any other institution in the country. There is a macroscopic view to this problem as well as a microscopic view.

I would assume that I would find a distinct difference in the distribution between these two ranges on the scale?

Dr. WATERMAN. That is my impression as I recall it, yes. In fact, that is one of the reasons why the curves of distribution in different parts of the country came out as they did, roughly in proportion to the number of active research people, to the number of college graduates, even approximately to the population, and the fellowships show much the same distribution. Under these circumstances the smaller colleges are bound to receive far less research funds, wherever they may be.

Mr. VIVIAN. My impression is NSF is doing a better job than the other agencies in this regard, and my remarks are not meant to deter this.

I would like to comment briefly on the split between the mission agencies and NSF. From my observations in dealing with the agencies, the principal merit of having them conduct basic research opposed to NSF sponsorship is not potentially obvious. I am talking here specifically about basic research as opposed to applied research, for example, advanced mathematics rather than applied mathematics. The defense agencies may not sponsor as much mathematics research as NSF, yet they do carry on a moderate amount thereof. The only basic reason I can see why they should continue it is that there is a requirement that members of these agencies, the personnel working in the agencies, be able to speak with reasonable effectiveness and be able to be conversant with modern fields. Therefore, the amount of research I would presume they would need would be the amount required to effectively educate the employees of the agency. Some of this is going to be done outside the agency because the personnel are so busy with their own internal programs and their own contract award work that they cannot do this, but they can benefit from external activity which is brought in to them as part of their contract work and effectively explained to them. It is an excellent procedure. I think it is a wise procedure. However, I would tend to expect the amount of research they support is well in excess of this amount. I, therefore, go back to the question of how much do they support.

Earlier this month I had a series of statistics on how much research was carried on by the several agencies. NASA research encompassed several dozen launch vehicles costing hundreds of millions because it came under a label of research. Under the sponsorship of other agencies, such as the AEC, DOD, and so on, the word "research" had a

different interpretation. My impression is that it was quite intentional that it was differently interpreted, namely, so there would be the least argument possible on the subject. If a uniform standard were applied, I think we would find a drastic restriction of those statistics, and we would find a totally different interpretation placed on this thing.

I am a strong believer that research and development needs to be done, especially that defense development needs to be done, but I am also convinced that more in basic research should be done in NSF rather than in the defense agencies. I think the criterion should be the basic education of the employees in the agencies and not the conduct of basic research.

I suppose if I asked anyone in NSF to provide me data on this subject, NSF would find itself in an embarrassing position; so, I won't do it. Who should I ask?

Dr. WATERMAN. I would say ask the agencies themselves why they are doing basic research.

Mr. VIVIAN. I have already indicated that will be a question I will ask, but I am not in a position to say whether I will believe the answers or not. Is there any third party?

Dr. WATERMAN. Such a question, if this becomes acute, would be a matter for study by the Office of Science and Technology. That is where the authority lies for this sort of thing. The coordination on these matters would take place in the Federal Council for Science and Technology.

I know just what you mean because I was for 5 years with the Office of Naval Research, which serves the Navy. The reasons for other agencies conducting and supporting basic research are important. Take the Navy's case. If basic research should be done entirely by the Foundation rather than by the Navy, the Foundation for example would never devote as much study to underwater phenomena as the Navy needs. The Navy needs that, and it needs it directly.

In other cases one can't always point to direct use so clearly. It is the agency's job to determine this, and the responsibility of the Office of Science and Technology, and the Federal Council as well, to watch it. One cannot lay hard and fast boundaries and say that only certain fields can be done by the Navy, for example, because requirements and opportunities change as time goes on.

Take the field of ornithology, bird study—do you think the Navy should be excluded from research in ornithology? Well, in the South Sea Islands if you knew their cries and habits tropical birds might give you an idea of what the enemy were doing. So, isolated studies can be important, but they have to make sense.

I think a protection against what you are concerned about is by providing more funds proportionately for basic research to the National Science Foundation, and, therefore, forcing the other agencies perhaps to be more selective. That would avoid some of the dangers you speak about.

Mr. VIVIAN. What I am concerned about is as follows. As I recollect, the price tag allocated to basic research is approximately \$1.7 billion. A sizable portion of this is for rather expensive facilities, and I will call the rocket booster a facility for the moment, so perhaps the real amount is about \$1 billion. A great deal of this is contracted in amounts of from \$50,000 to \$250,000 at a time. I may not have the right

median, but I would expect the median of $200,000 is probably not far from the fact. That means if you were to evaluate all the proposals, you would be evaluating approximately 5,000 or 6,000 proposals. I cannot see how the Office of Science and Technology, Dr. Hornig's Office, could efficiently evaluate 5,000 or 6,000 proposals as to which agency each should belong. I think it is beyond the capacity of the Office. Therefore, I presume there are guidelines which exist as to what is NSF-related, DOD-related, and so forth. Are those guidelines written down? Does a contracting officer in, for example, the Office of Aerospace Research have a set of guidelines as to what he is not to fund in OAR and what he is to transfer to NSF?

Dr. WATERMAN. I think one would have to ask the individual agencies whether they have such guidelines internally. I don't know that there are any external instructions on this other than their mission and the Executive Order 10521 I mentioned earlier.

My former remarks were answering the first part of your question. Let me answer the second part; how does one establish a way to keep such an agency from getting too much research funds? One is by the total budget of the agency which is generally under pressure to stay limited, and the vital things to the agency are their actual operating programs, not basic research. So, in the course of time, basic research is one area that begins to be squeezed. This provides a corrective measure. In the case of a new agency like NASA this effect has not had time to take place; they have to go ahead with basic and applied research for their new developments. NASA represents an outstanding case in the difficulty of determining basic research costs. If one is sending up a satellite or a probe for basic research purposes, obviously the equipment in the vehicle should be assigned to basic research. But what about the operation of launching the vehicle, which is a heavy cost? What about development of the vehicle that is used to get it up? Should this be included in the cost? So, there is a real problem here to arrive at accurate and comparable research costs.

If I am not mistaken, the decision in these cases is not to put in the developmental costs of a vehicle that can be used for other purposes and which happens to be used for basic research, but a vehicle that is designed exclusively for basic research should have its cost chargeable to basic research.

As a partial solution I believe that sums like this should be placed in a different category than the support of basic research such as the regular programs of universities. If they are separated out and put by themselves, then they can be judged more accurately.

It is a troublesome question—what one can do about a very costly installation which is necessary to do certain basic research and does not represent the actual cost of doing it.

Mr. VIVIAN. I would like to ask Mr. Yeager to inquire into the guidelines used in these various agencies by the contract administrator, specifically, as to the letting of the contracts, which would be in their purview or not.

I would suppose as to these agencies, such as OAR, there would have been a fair number of times when a certain research activity which they would have liked to have funded under their budget has been squeezed out by the pressure on the total budget. They may

say: It is something we are in favor of, and we would like NSF to carry this under their aegis, if possible. Does this occur frequently?

Dr. WATERMAN. I am not up to date on this, but it has happened repeatedly in the past. ONR pioneered in basic low temperature physics and AEC picked it up as well. Later both agencies didn't feel they could justify it sufficiently, and they both asked NSF to take over.

Mr. VIVIAN. Does this characteristically happen?

Dr. WATERMAN. Oh, yes.

Mr. VIVIAN. It has not been impeded by any internal agency attitudes?

Dr. WATERMAN. It is hard to make a statement about that. Some agencies might occasionally want to hold onto some research perhaps longer than appropriate, but primarily this is a matter between the agency and its research office.

Dr. HAWORTH. As the growth of the budgets of the mission-oriented agencies, particularly, not so much NIH but others, has tended to level off, it has happened more in a little different sense than you are talking about. Not necessarily that OAR has said it is not appropriate for research in this field, but it doesn't have enough funds to support as many programs as, say, it has been carrying on, and in recent years the NSF has taken over several such programs in nuclear physics, for example. We are presently discussing with OAR the possibility of our taking over the operation of the Arecibo radio astronomy installation in Puerto Rico and various more of the nuclear physics and some of the materials programs and things of that sort.

Mr. VIVIAN. Certainly OAR should receive a great deal of credit for its work in radio astronomy in years past.

I would like to comment to all of my scientific cohorts of years past who feel that a single agency has control over all funds on a given subject, have made a tremendous mistake. I am equally adverse to these mission groups being cut out of the picture. I think the relative percentages should be adjusted in some reasonable way.

I have nothing further, Mr. Chairman.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. No questions.

Mr. DADDARIO. Dr. Waterman, since Reorganization Plan No. 2 transferred some of the NSF functions to OST in the field of evaluating scientific research programs undertaken by agencies in the Federal Government, the question arises whether OST and its staff in fact have that capability. Mr. Vivian has again raised that particular question. Would you care to comment?

Dr. WATERMAN. I should say that what this really did was to transfer the evaluation of agency programs to the OST. It still leaves to the Foundation the development of national policy with respect to science, in particular as a help to OST.

In any such evaluation the Office of Science and Technology in the first place has the help of the Federal Council for Science and Technology for mutual review of agency programs and the problems which they raise. This gives a concerted Federal view of what the agencies are doing. Then, it has the President's Science Ad-

visory Committee, which, of course, cannot regularly go into great detail but can consider critical problems and is extraordinarily expert in its insight into research quality, and the ways in which science at a given time is moving most significantly.

Evaluation in detail is, of course, a huge job. It cannot be done project by project. There are too many of them. I don't know what the total is now in the Federal Government, but it is well up in the tens of thousands. It must be done by categories, and within the categories, brought to the attention of expert panels. To begin with, the agencies should be sharply aware of their responsibility for their own review in the formation of their programs, their use of advisory committees and how well they exercise judgment in carrying out their programs. That is to say, at the start is the best place to begin this evaluation. Each agency should be held responsible for doing an excellent job there.

Then without actually reviewing the programs of the agencies one can judge the competence of the advisory process and the competence of the staff.

Personally, it seems to me we are embarking on a very sound procedure right now in the thorough review by the committee headed by Dr. Kistiakowsky, and by a panel of the President's Science Advisory Committee doing likewise in the overall picture. The program has reached a size and cost now which make this highly advisable.

However, we should not find it necessary or desirable to do this year after year. The effort is too great in time and money. In the meantime I should like to see increased use of the experienced science administrators in Government taking their share of this appraisal, first, by their responsibility to their own agency programs, and, second, by greater use of the cooperative techniques that I spoke about which the Foundation has used quite extensively; namely, by agency science administrators in the different disciplines keeping in close touch with their opposite numbers. In this way by closer association among them, better quality standards are achieved, and these administrators themselves are better able to ride herd on the quality and kind of research in their own agencies. Thus by internal community effort one can achieve a valuable kind of review and improvement. This can be made more formal if it seems desirable. I think it ought to go fairly well without formal organization. For example, the head of the research program in the Foundation in physics, chemistry, or psychology could have meetings with his opposite numbers in the other agencies, and they could determine pretty well as an interim measure the quality and distribution of Federal support in that field. I think this would be helpful, and it would obviate the necessity for frequent elaborate reviews like the present one. These intensive reviews ought to take place only at rare intervals so as not to make excessive demands upon the time of the ablest research men of the country. Such a procedure could greatly help the Office of Science and Technology. In this way the latter could decentralize its efforts to some extent and avoid having to acquire such a large staff.

Mr. Daddario. What you are suggesting, then, is periodic reviews but more formalized meetings of the responsible people?

Dr. WATERMAN. Yes; closer communication and cooperation at least, formality to the extent that is necessary, and to some extent perhaps delegation of this function by the OST.

Mr. DADDARIO. Whether that evaluating function is in the hands of the National Science Foundation or the OST, as it now is, it would not in any serious way affect the ability of NSF to formulate policy in this regard because the information would be equally available?

Dr. WATERMAN. Right.

Mr. DADDARIO. Dr. Waterman, I appreciate your testimony, and I hope we might have occasion to send some additional questions to you.[1]

Dr. WATERMAN. I would be very glad to answer them, Mr. Chairman.

Mr. DADDARIO. Mr. Yeager.

Mr. YEAGER. Dr. Waterman, would you make the same recommendation you made about keeping basic research spread among the various agencies in connection with the support of science education?

Dr. WATERMAN. No; not in the same way.

Mr. YEAGER. To some extent at the present time the various agencies have fellowships and training programs.

Dr. WATERMAN. I would be very careful about this. It seems to me an agency with a practical mission should in the first place deal only at the graduate level where research is the important thing and its plans should be carefully coordinated with NSF for science, and for other fields with the Office of Education. I also believe they should have the privilege, for example, of establishing special fellowships in an area of interest not adequately covered in general fellowship programs such as those of the NSF. In that sense it would correspond somewhat with the basic research policy. I don't think they should deal with undergraduate activities, nor with secondary and primary schools. I believe their educational support to academic institutions should be confined to cases where the institution could profitably use a laboratory or other unit devoted to special research in their field. This should be looked at with a great deal of care, however, and action taken only when fully endorsed by the institution as a policy matter. The extent to which special institutes or research centers need to be set up is another policy matter, and whether they need to be associated with a university or not. I believe the possibilities exist, but action should be taken only with a great deal of care and judgment.

Mr. YEAGER. Do you think this should be coordinated with NSF to some extent since the need will depend somewhat on the data NSF has collected?

Dr. WATERMAN. Yes; definitely.

Mr. YEAGER. You stated you felt that more use should be made of the National Science Board by other councils of the Government, did I understand you correctly, or did you mean in the Foundation structure?

Dr. WATERMAN. I meant that more use could well be made of the National Science Board as to national policy with respect to science and in educational institutions, not necessarily confined to the NSF structure. Possibly it could be useful to the Office of Science and Technology. The Board is a unique body. It has an extremely dis-

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

tinguished and able membership for purposes such as Government-university relationships. Now, I don't know in what connection this might be most useful. My first thought is that it could be very much so in Government-university relationships, in the support of research and education in science. But it is a body which is unusual in its competence and representation.

Mr. DADDARIO. Thank you, Dr. Waterman.

This committee will adjourn until 10 a.m. tomorrow at this same place.

(Whereupon, at 12:07 p.m., the meeting was adjourned to reconvene at 10 a.m., Thursday, July 1, 1965.)

NATIONAL SCIENCE FOUNDATION

THURSDAY, JULY 1, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10:20 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., the Honorable Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order. Our first witness today is Dr. Dael Wolfle, who is executive officer of the American Association for the Advancement of Science, the large national membership society that represents all fields of science. He received the bachelor of science and master of arts degrees from the University of Washington, in Seattle, and his doctor of philosophy degree from the Ohio State University in 1931.

Dr. Wolfle, we are happy to have you with us, and we look forward to hearing from you.

STATEMENT OF DR. DAEL WOLFLE, EXECUTIVE DIRECTOR, AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

Dr. Wolfle. Mr. Chairman and members of the committee, the National Science Foundation has become the standard source that is used by all of us who are interested in statistical information on the Nation's scientific and engineering manpower and on financial information concerning the research and development effort. An explanatory footnote crediting the National Science Foundation as the source is found in countless tables published in congressional committee reports, reports from other Government agencies, from industry, in the public press, and in scholarly papers and monographs dealing with research and development or scientific manpower. All of us who use such figures are indebted to the National Science Foundation, for the amount and detail of information available now are very much greater than could be found anywhere a dozen years ago.

But those of us who want and use such information are not satisfied. We would like to have more, we would like to have it in greater detail, and we would like to have it more promptly. There are several reasons for these feelings of dissatisfaction, some of which may be under the control of the National Science Foundation and some of which are not. I wish to mention four of these reasons.

51-204—65—vol. 1——12

First. The questions that we can ask outrun the information that is available. No matter how hard the National Science Foundation, the Bureau of the Census, the Office of Education, the Bureau of Labor Statistics, and the other agencies that provide statistical information work, we can always think up new questions that they have not anticipated. As a result of these pressures and their own initiative, NSF and the other agencies have greatly expanded their statistical reporting services. The annual series known as Federal Funds for Science, which is the standard reference source for information concerning Federal expenditures for research and development, started as a slim little publication of some 40 pages. Now it takes some five times as many pages of finer print. The occupational classifications used by the Bureau of the Census have become increasingly detailed. The U.S. Office of Education reports the numbers of academic degrees awarded in much finer detail than formerly.

The reports published by NSF and the other agencies are, therefore, increasingly complete, increasingly detailed, and increasingly useful. Yet it still remains true that we can think up new questions that are not answered by the published reports.

Second. The second reason is that neither NSF nor any of the other agencies can possibly ask for all of the information that someone may wish to have tabulated. Restraint is necessary. To collect data for the National Register of Scientific and Technical Personnel, the NSF sends a long questionnaire to a large number of scientists and engineers. The Office of Education sends questionnaires to every college and university in the United States. It takes time, and sometimes it costs money, to supply the requested information. The collection is always a burden on the original sources. Restraint is necessary, or those sources will simply balk and refuse to cooperate.

Third. Some of the questions that are of particular interest deal with future trends and projections. We would like to know how many degrees in engineering will be conferred in 1970, or what the demand will be for chemists next year. Trends can be projected and estimates can be made, but a number of assumptions are always involved in these processes, and some of the factors that will turn out to be important in influencing future trends cannot be accurately predicted, and others cannot be foreseen at all. In addition to these inherent limitations, it is also true that the methodology for projecting manpower trends, particularly on the demand side, is not well developed.

Fourth. The fourth reason for dissatisfaction with the information available results from the very nature of the situation. One of the reasons for dissatisfaction is delay. Publications on finances and on manpower usually report the situation as of 1, 2, 3, or more years ago. There are many opportunities for introducing delay into the system. When NSF mails the National Register questionnaires to American scientists and engineers, some of them are busy, some are off on field trips, some are in Washington for committee meetings, and so there are delays in returning the original questionnaires. When information is sought from universities, it frequently takes a considerable amount of time to compile and transcribe the requested figures. When information is sought from industry, it may be necessary to translate from the recordkeeping system used by a particular company to the system used in the questionnaire.

After the questionnaires are returned, a considerable amount of time is required for tabulating and editing the data, for checking discrepancies, in waiting for tabulating machine time, in waiting for review and approval, and in getting the reports printed. Some of these delays could be reduced, but they can never be eliminated.

Another aspect of the nature of the situation is the fact that statistics of interest are collected by a number of different agencies. Among the Government agencies, the chief ones are the National Science Foundation, the Bureau of the Census, the Bureau of Labor Statistics, and the Office of Education. In 1958 a special advisory panel to the National Science Foundation and the President's Committee on Scientists and Engineers prepared a report entitled "A Program for National Information on Scientific and Technical Personnel." That report, which is generally known as the Hauser Committee report, led to various governmental considerations which eventuated in naming the National Science Foundation as the focal agency for coordinating the scientific and specialized manpower statistics gathering and reporting activities of the several Government agencies. Designation of NSF as the focal agency was a useful step in improving matters, but "focal agency" is a status that has no teeth or police power. The Foundation can coordinate the activities of the other agencies only by persuasion and through voluntary agreement. This is perhaps all that should be attempted, but we should recognize that no one has really given high priority to the job of collecting, maintaining, and reporting statistical information concerning the Nation's scientific and technical manpower. The National Science Foundation has not, nor has the Bureau of the Budget, nor has Congress. Work must be done when and as personnel are available, and must be laid aside when jobs of higher priority arise. Let me cite one example.

In the Hauser Committee report of 1958, it was agreed that it would be highly desirable for the Bureau of the Census to make a special study of a sample of the persons identified in the 1960 census as having earned college degrees or as being engaged in scientific and technical occupations. It was generally agreed that such a study would be of widespread value, and planning for it started in 1959.

The basic census data were collected in 1960, but the Bureau of the Census then had to devote its time to the tremendous job of getting the major census information ready for publication. It was therefore not until 1962 that the Bureau of the Census, under a grant from the National Science Foundation, could start collecting the data for this important special study. The questionnaires were distributed and collected in 1962; tabulation plans were made in 1963; the tabulations were completed in 1964. The first analysis of these data should be available shortly. And perhaps by the end of 1965, but more likely some time in 1966, we will have a valuable source that we would have liked to have seen in 1961.

When one is dealing historically with such information, it is more important that the data be accurate than that they were published quickly. But one also wants to have data available that will be useful in shaping policy now, that will be of greater value in projecting the future, and that will help us to decide what actions we should be taking this year and next. For these purposes, greater promptness is necessary.

There are four recommendations I wish to make to decrease the delays and to increase the usefulness of the statistical program.

1. The first concerns priority. Gathering and publishing statistics is not the most important job the National Science Foundation has to do, but personally I believe it merits a higher priority than it has been receiving. On this point we must make a choice. If we agree that the statistical information is inadequate and becomes available too slowly, we know how to give this function a higher priority. If we do that, we can, as one example, ask the National Science Foundation and the Bureau of the Census to start soon to arrange for the collection of data in connection with the general census of 1970 that will allow prompt publication of a special analysis of scientific and technical personnel and of the Nation's college graduate population.

If, on the other hand, we do not believe that these data-gathering responsibilities merit any higher priority than they have been receiving, we ought to stop complaining about performance and delays.

2. The delay in handling manpower data could be reduced somewhat if data processing equipment of higher speed and capacity were available. As I pointed out earlier, some of the delay is unavoidable. Still, faster reporting would be possible with better equipment.

3. I recommend that NSF be asked to study the feasibility of collecting a different kind of manpower information, a kind that I will call "flow" information to distinguish it from the information on current status that is usually collected and reported. Most scientific manpower studies are like the decennial census in that the data collected deal with the status of the whole group at a particular time. Thus the periodic surveys of the National Register of Scientific and Technical Personnel answer such questions as: How many astronomers are there? How many chemists have doctor's degrees? How many biologists are employed in industry? These are the same kinds of questions that are answered by the decennial census.

The Bureau of the Census supplements this status information by conducting a large number of studies of small samples of the total population to secure current information on geographic mobility, occupational changes, and other important trends and changes.

Similarly, it would be possible to supplement the periodic studies of the National Register by sampling studies that would give current information on transfers from industrial to academic positions, and vice versa, from one region of the country to another, from one area of science, such as physics, to a neighboring area, such as electrical engineering, or from employment to retirement.

The Federal Government has a greater need than anyone else for up-to-date information of this kind. In considering new legislation or new programs in which science and engineering are involved, account is taken of the number of dollars required and of the facilities that are available or must be constructed. Account is also taken of the human resources required and available, but the evidence is usually much poorer than that available concerning costs and facilities.

Let me cite an example. A few years ago, the President's Science Advisory Committee saw a need for a larger number of persons with graduate training in engineering, mathematics, and the physical sciences. Congress agreed and provided a larger number of graduate fellowships, traineeships, and loans. Let us accept, therefore, as the

first element in a complex problem, the need to stimulate a large number of students to secure graduate training in engineering, mathematics, and physical sciences.

The second element concerns the faculty. It was widely believed that not enough of the new recipients of doctor's degrees in engineering, mathematics, and the physical sciences were entering college and university teaching and that too many experienced faculty members were deserting teaching for research or industry.

As a third element in the situation, there was some indication that, due to lack of laboratory facilities and for other reasons, the university teachers were not training as many graduate students as they might.

Obviously, these three elements are interrelated. If the faculty is insufficient, either the number or the quality of graduate students will suffer. If the faculty is not training as many graduate students as might reasonably be expected, better facilities and internal changes in the educational system could produce a larger number of new doctorates, even without an increase in faculty size.

These general relationships seem clear enough, but data on the quantitative relationships that would have been helpful in deciding how many additional fellowships and traineeships to provide were quite inadequate. So the decisions had to be made largely on the basis of assumptions rather than hard facts. This is often the case in dealing with manpower questions.

This particular situation inspired Richard Bolt to develop an interesting mathematical analysis of the feedback of new Ph. D.'s in the sciences into the educational system, a model in which he could state quantitatively some of the relationships involved. The model that Dr. Bolt and his colleagues developed (Science, May 14, 1965, pp. 918–928) brings some interesting new thinking into our consideration of scientific manpower trends and studies, but I call attention to the fact that the actual data that Dr. Bolt could use were 2 to 4 years old when the analysis was published. Up-to-date information of the kind that I am advocating would make such models distinctly useful in deciding on policies and programs concerning future needs, desirable levels of fellowship programs, the need for teachers, the planning of facilities, and similar matters.

4. My final recommendation is that it is time for a new kind of agency or partner in the field of scientific manpower studies. From 1950 to 1954, I directed such an agency. It was financed by the Rockefeller Foundation and worked under the sponsorship of the National Academy of Sciences, the American Council of Learned Societies, the Social Science Research Council, and the American Council on Education. The studies that we conducted dealt broadly with the whole set of problems of the identification, education, and utilization of talent in the United States, and in some ways constituted a pioneer exploration of the whole area of specialized manpower. When we finished, we went out of business. We discussed the possibility of seeking continuity, but decided that the time was not ripe. Now another study of a somewhat similar nature is being started under the auspices of the same four groups and with financial support from the Carnegie Corp. and the Russell Sage Foundation. It too is established on a temporary

basis, and presumably will go out of existence in 2 or 3 years when its report is completed.

I propose that it is now time for a permanent agency of this nature. There are some problems that cannot be well handled as part of regularly scheduled data gathering and publishing operations. The National Science Foundation is under too much pressure to maintain the schedules of its periodic reports, and it is called upon too frequently to provide special analyses and tabulations to congressional committees and other agencies of Government, to allow it to give adequate time and thought to some of the methodological studies that should be carried out, to the interpretation and meaning of trends, or to the synthesis and correlation of studies carried out by several agencies. As a single example of the kind of work that this proposed organization might undertake, there is need to improve the methods of projecting future manpower demands. There are some ideas as to how projections might be improved, but no one has had time to try them out.

It is unlikely that such studies will be carried out by the operating staff of NSF or any of the other agencies, but they would be appropriate for the kind of new agency I am proposing. I would suggest that this agency be a step or two removed from operational responsibility. One thinks of the Institute for Defense Analyses or the Rand Corp. as roughly analogous models, or of an agreement with the National Academy of Sciences as a possible mechanism. If such an organization is established on a continuing basis, it should have some Government support, but it would be eligible for and undoubtedly would also receive support from nongovernmental sources. It would be a strong ally to the statistical groups in the National Science Foundation, the Office of Education, the Bureau of the Census, and the Bureau of Labor Statistics. Working in cooperation with those agencies, it could conduct supporting research. It could integrate and interpret some of the data gathered by those agencies. It would sometimes serve in the useful role of external critic. It could work to improve methodology in the field.

Eleven years ago my colleagues and I decided that the time for such an organization had not yet arrived. Since then, NSF has developed a valuable series of statistical records about the Nation's scientific manpower; other agencies have extended their services: a number of special studies have been carried out by Government and private groups; and the interest in and need for fuller and more accurate information have all grown to the point that I now consider such a supplementary quasi-governmental institution most highly desirable.

In conclusion, I want to repeat the first point I made: we are much indebted to the NSF; the information that is now available is both greater in quantity and better in quality than any of us had before NSF started. Yet further improvements are attainable. If you believe that better and faster data handling are desirable, my first recommendation is that the statistical responsibilities of NSF be given higher priority. Give the National Science Foundation a push, and help them, as the focal agency in this area, to push the other agencies.

I would also recommend that serious attention be given to the problem of securing better data-handling equipment and to the development of a new kind of manpower study that would secure up-to-date information on the flow of scientific manpower from one kind of em-

ployment, scientific field, or set of characteristics to another, to supplement the kinds of information that have been available, and to provide more timely information to use in making policy and operational decisions.

Finally, the time has now come to establish on a semipermanent basis a new agency that will not have as its primary function the collection of data, but that will be chiefly engaged in interpretation, synthesis, criticism, and the improvement of methodology.

Mr. DADDARIO. Dr. Wolfle, you have recommended the establishment of a new agency. Would you discuss that in relation to the ability of NSF to perform this function within the original charter granted to it by the Congress?

I recognize that you have indicated the pressures under which the National Science Foundation now operates, which might inhibit it from performing this particular function. However, if it were to be given the proper funds and the opportunity to do this, would this not meet your requirements?

Dr. WOLFLE. It could well be established with the National Science Foundation. I think it should be differentiated sufficiently from the data-gathering and reporting activities so that it would be free to do this slightly different job.

Mr. DADDARIO. The reason I ask this is because your recommendation would put it on a quasi-governmental basis with the opportunity to have funding from the private foundations from time to time. Because there are problems in that regard, and since studies to date have indicated that this kind of a program would be helpful, the question that comes to my mind is that this is a function the Government should provide on a continuing basis. The funding should be regular and not intermittent, as it obviously has been to date, where after a study has concluded there is a vacuum for a number of years before there is another study. It seems this might be the course that would develop if we were to follow the suggestion for an organization on a quasi-governmental basis.

Dr. WOLFLE. In suggesting the Institute for Defense Analysis and Rand as possible models I did not have in mind the size of their budgets but the one step removed from operational responsibility that allows them to be thoughtful allies to the participants in the Department of Defense or the Air Force, with which they work most closely. It would be possible to establish this new function wholly within the National Science Foundation, and it might work just as effectively there. The suggestion I made was to provide the insulation from putting out day-by-day fires that you can get by removing it, but the function is more important than the agency.

Mr. DADDARIO. Yes, I would gather from your statement that the important thing that you have recommended is the accomplishment of this purpose and not necessarily how it is done. You are not criticizing the National Science Foundation for not doing this because you do recognize that it does have these other requirements. You are saying that if it be done, it should be separate and apart from its other statistical gathering duties and requirements; is that correct?

Dr. WOLFLE. Yes.

Mr. DADDARIO. In an editorial in the June 25 issue of Science you referred to the applications of science. I wonder if you might go into

that a bit and tell us how you see the National Science Foundation in that context.

Dr. WOLFLE. That editorial probed in several different directions. My own judgment on that point is that the applications of science are so heavily the responsibility of many of the other agencies, the National Institutes of Health, the Department of Defense, the Atomic Energy Commission, NASA, that better balance overall is likely to be maintained if NSF does not have to become an agency primarily interested in applications. If it can retain its emphasis and center of interest in science, the whole effort will be better served than if it, too, would have to move into applied interest.

Mr. DADDARIO. Your feeling then is that it should resist the idea of becoming involved in the applied fields but stay in the pure sciences and bolster up its activities in the field of education. Applications should be left to the other agencies involved in the applied and developmental fields. This would keep NSF probably constricted somewhat in its growth, but heading in the direction toward which it could do its best job in the scheme of things?

Dr. WOLFLE. This would be my judgment; yes. Now, this isn't to say that the applied activities are not important. They are perhaps in some respects more important than we have been recognizing. But in terms of the maintenance of balance and in terms of fostering the scientific base upon which the applications rest, I would not move it in the direction of an applied agency but would follow the course you have stated.

Mr. DADDARIO. I recognize that does not mean that you downgrade the transfer of knowledge into the applied areas.

Mr. Conable?

Mr. CONABLE. No questions.

Mr. DADDARIO. Mr. Vivian?

Mr. VIVIAN. Yes, I have a question regarding manpower. I am fairly familiar with the problem of training persons from other fields to be involved in science to meet any sudden increase of effort. I am curious to know, however, what your experience has been with having persons transfer out of scientific and engineering careers into other careers. Do you have any statistics on how often this happens, and the results that occur, and so on?

Dr. WOLFLE. I cannot give accurate figures, but qualitatively, yes. In general, the more lengthy and advanced training a person receives, the less likely is it that he will transfer into some other field. Thus, there is a much smaller transfer out of medicine into other areas than there is from engineering. There is a smaller transfer by those people who have reached, say, the doctorate level than those who stopped at the master's or bachelor's level.

Secondly, there is the problem of whether or not an actual transfer has occurred. The number of people who gets bachelors degrees in the sciences is much larger than the number of people who ever go to work in positions that one would class as scientific fields. This is also true of history, economic, philosophy; that is, the scientific undergraduate training is in a sense a kind of general, useful education, but is not necessarily vocational.

I don't know whether I have gotten at what you wanted.

Mr. VIVIAN. My concern is as follows: The physicians, the medical doctors, are generally in short supply; at least I think they are. There may be some arguments about that by the A.M.A.

The physicists are in a supply determined almost totally by allocations in these buildings. I think if we were to drop the allocation for science by, say, 30 percent, there would be an enormous oversupply of physicists, since most are hired by the Government.

The question I am concerned with is the extent to which persons who are no longer employed on Government contract activity are absorbed into the surrounding economic activity of the Nation. Has there been any surplus of engineers and scientists at any time within the last few years which has been unabsorbable?

Dr. WOLFLE. There have been some reports of surpluses when major changes were announced in defense contracts; and surely, when there are substantial cutbacks, there are individual people who are on the market and have to hunt for new posts. In a particular case, which attracted quite widespread attention, my information is secondhand; but, from some of the engineering organizations that did investigate, the people of quality were very rapidly snapped up by other companies, and it was the more marginal ones who were having the greatest difficulty of reemployment and who were——

Mr. VIVIAN. It is my impression that, after this recycling occurs, those persons who are dropped off the rolls are employed, often many thousands of miles away from the particular company which had dropped employment. They have very little difficulty in moving to other parts of the economy. Would you say this is correct or not?

Dr. WOLFLE. In general this seems to be true, yes, in our experience at least of the last 20 years.

Mr. VIVIAN. So the fluctuations in the budget support probably do not cause any great impact upon the economic welfare of these people?

Dr. WOLFLE. The people we are talking about are intelligent, educated, and geographically mobile in general, and there is at the same time a large amount of flexibility in whatever we mean by demand or need, so that there is room to move into adjoining kinds of work or freedom to move to other parts of the country, so that one hasn't had to worry about unemployment.

Mr. VIVIAN. Thank you.

Mr. DADDARIO. Mr. Roush.

Mr. ROUSH. Doctor, I read your testimony last evening, and I had one question which came to mind as I read your statement. It concerns your second recommendation that the delay in handling manpower data could be reduced if data-processing equipment of higher speed and capacity were available. I assume you refer to the National Science Foundation. Is this correct?

Dr. WOLFLE. I believe that both the National Science Foundation and the Office of Education, which process large amounts of data, are now studying their own needs and what newer and better equipment would aid them.

Mr. ROUSH. Are you familiar with the equipment which the National Science Foundation has?

Dr. WOLFLE. Not in detail.

Mr. ROUSH. Isn't your recommendation directed to the data-processing equipment of the National Science Foundation?

Dr. WOLFLE. Yes.

Mr. ROUSH. The reason I ask is that when Dr. Hornig was testifying before the committee, I specifically asked him the question as to whether or not the National Science Foundation had the most modern equipment and tools necessary for the collection and dissemination of scientific information. His response was that they did have. Therefore, there is a conflict between the two opinions.

Dr. WOLFLE. It certainly sounds so. I may be misinformed. As I say, I am not familiar in detail with the equipment they have. I have discussed this question with some of the members of the NSF staff, and have from them the report that they are studying what they could do to have better equipment for their own needs.

Mr. ROUSH. If you should obtain information which would show a deficiency in this type of equipment, I am sure the committee would appreciate it if you would convey that information to us. We would also appreciate hearing any recommendations you may have as to specific types of equipment which the National Science Foundation might use to better its program.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Doctor, it is possible also, is it not, that if they have this equipment, they are not using it for the priorities that you would deem most desirable? If you are going to check into it, this is something we would be interested in knowing. NSF may have very good data-processing equipment, but have not the time nor the personnel to use it in the matter for which you are seeking information.

I would like to ask you this, although it is not directly related to your testimony. There has been testimony by Dr. Teller and others recently that we have put so much emphasis on basic scientific research that we are neglecting applied science, and that as a result we may have lost our leadership in the applied scientific field.

From your point of view, is this trend detectable? Are many of our best people so immersed in basic scientific research now that we are not making the best use of our technology? Is that a manpower problem?

Dr. WOLFLE. I am not sure it is a manpower problem as much as a problem of interest and motivation. Basic science has certainly been receiving both financial and moral support to such an extent that it has become a more glamorous field than it used to be. There is, however, a great deal of work going on in applied areas. I think that the complaint that Dr. Teller and others have made might better be stated in terms of balance or application to civilian needs rather than an overall disregard of applied research and development.

We have been concentrating most of the applied activities on specific fields, and various commentators note gaps and discrepancies to which they would like to have greater attention given, chiefly in the nondefense, nonspace applications.

Mr. CONABLE. Does the National Science Foundation make a significant contribution to this trend toward basic research?

Dr. WOLFLE. Well, to the extent that the National Science Foundation has become large enough to be a significant contributor, which it now is, to the support of basic research, yes, it may. But the National Science Foundation money for basic research is still a relatively small fraction of the total amount that is going into this area, and it is still

true that although most, roughly two-thirds, of the total research and development funds come from the Federal Government, industry itself is putting several hundred million dollars a year into basic and applied research.

Mr. DADDARIO. Just following up on that point, however, the fact that the National Science Foundation contributes to this raising of the status of basic research is something which is good, and certainly we ought not to depress it. The hope, however, is that we can stimulate better ways to transfer the knowledge to everyday uses.

Dr. WOLFLE. Yes. We are all better off because of what the National Science Foundation has done to stimulate basic research, even if that has drawn some people away from applied interests.

Mr. DADDARIO. We are doing a good job in the transfer of knowledge, but we could do a much better one than we are.

Mr. Yeager, do you have a question?

Mr. YEAGER. Yes, Mr. Chairman.

Dr. Wolfle, on page 4 of your statement you say that we should recognize that—

> no one has really given high priority to the job of collecting, maintaining, and reporting statistical information concerning the Nation's scientific and technical manpower. The National Science Foundation has not, nor has the Bureau of the Budget, nor has Congress.

Do you think it would be helpful to amend the organic act of the Foundation to give greater emphasis to this function? I am particularly referring, as a possibility, to language something similar to that which was used in an Executive order dealing with the administration of scientific research in 1954. This enjoins the Foundation:

> To continue to make comprehensive studies and recommendations regarding the Nation's scientific research effort and to treat sources for scientific activities, including facilities and scientific personnel and its foreseeable scientific needs, with particular attention to the extent of the Federal Government's activities on the training of scientific personnel.

I am not suggesting this particular language, but something of this nature. Do you believe that it would help to have Congress give a further directive to the Foundation in this regard?

Dr. WOLFLE. Not unless you go beyond that. I doubt if just changing the wording would aid greatly. The organic act now specifies that the Foundation shall maintain a register and that it shall serve as a clearinghouse for information about the Nation's scientific and engineering personnel. It has been doing these jobs. It is in a sense a service function rather than a primary aim of the Foundation. It serves as a national source. It serves as a governmental source, and it serves as a basis for its own internal policy planning.

I would like to see it given a higher level of attention, a higher priority, and I may be wrong in thinking that a modification of the act would be insufficient.

The conclusions to which you come in the report you prepare here and the way in which the budget of the National Science Foundation is handled would be, I think, effective means of increasing priority. The total amount of money spent by the National Science Foundation in this area is, if one includes all of the policy studies, the nonstatistical as well as the statistical, of the order of 1½ percent of its current

budget, which seems to me to be a nonexorbitant level of expenditure to maintain a continuing body of information about the financial aspects, the manpower aspects, and the trends, for its own affairs and for all of the other governmental interests in manpower.

I think they could effectively use more money, and if I could take my choice, I would take more money rather than a change in the wording.

Mr. YEAGER. The Foundation could now allocate a greater percentage of its funds to this area, perhaps at the expense of something else?

Dr. WOLFLE. Yes.

Mr. YEAGER. Would you estimate that, say, 2, 3, or 4 percent would be a fair figure to get some of the things done that you have mentioned?

Dr. WOLFLE. Yes.

Mr. YEAGER. Thank you, Mr. Chairman.

Mr. DADDARIO. Dr. Wolfle, I refer again to your editorial on the 25th of June. You mention another possible change being that the Foundation should be given broader responsibility in the field of higher education. In your article you commend, and in a sense compliment, the agencies for working closely together in this regard. Then you say, and I would like to quote the last sentence of that paragraph:

> The next step could be a union that would frighten some of the interested parties and appear to others to be a new frontier of intellectual leadership undreamed of when the National Science Foundation was planned or established.

What type of union do you have in mind?

Dr. WOLFLE. It is, I believe, clear that the Federal Government will continue to have a larger role in educational matters over the Nation as a whole than it has had in the past. The whole series of legislative decisions of the past decade or so have extended the Federal interest both in amount and also in terms of the areas of interest or responsibility.

Somehow or other the responsibility has to be divided; it can't all be lumped under a single agency. We now have a National Science Foundation which deals at the advanced graduate, the college and, to a smaller extent, the precollege levels. We have an Office of Education that deals with nonscientific activities, but overlaps both into science in some of its fellowship programs and extends from the very elementary up through the highest levels. We probably will have Federal support for the humanities in the Humanities and Arts Foundation that now looks like a likely possibilty. It is possible to divide these several functions by field of interest or discipline; that is, the humanities on the one hand, the sciences on the other hand, other aspects somewhere else. It is possible also to make divisions in a horizontal sense as between levels of education.

What I was striking at there was the possibility of a more centralized interest in scholarship, in education at the higher levels as one means of dividing this responsibility.

Now anyone whose particular interest is in a given area would, I think—or some people whose particular interests are in a given area, would object to such an amalgamation. Some scientists wouldn't want to have their agency diluted by also being responsible for humanities,

or arts, or the social sciences, and some humanists may not like to play second fiddle to these other areas, and the Office of Education might be reluctant to give up some of its responsibilities.

But, as one trend to be developed over a span of years, I think we ought to consider the possibility of an office, an agency, or some title at relatively high level, that would have as its focus the maintenance of scholarship and education and research in the broad sense without too much worry whether the particular field be called history or botany or political science or physics or art.

This is a controversial subject, but it is one of the possible directions.

Mr. DADDARIO. It is a very interesting idea. I think it is one of the things that the Congress has to be constantly informed about because it is a matter of controversy in a sense. We have had occasion to talk to educators from time to time, and at the moment it would seem that the consensus in this area would indicate that the growing responsibility in each of these agencies is a good thing. However, an amalgamation of them could in a sense eliminate the competitive ideas which generate from each of the agencies. This is the controversy, I imagine, to which you refer.

Dr. Wolfle, I am grateful for your coming here and appreciate, too, the advice you have given us today. You have been an excellent and exciting witness, and the committee is grateful to you.

Our next witness is Dr. Chalmers W. Sherwin, Deputy Director of the Defense Research and Engineering (Research and Technology) for the Department of Defense. Dr. Sherwin is replacing Dr. Harold Brown as our witness today. Although we regret that Dr. Brown could not appear, we wish to have you know, Dr. Sherwin, that we are pleased you are here. Please give Dr. Brown our best, and thank him for having made arrangements for you to come. We know of the work you have done in DOD and we are aware of some of the testimony you have provided from time to time before other committees of the Congress. We are looking forward to your statement.

STATEMENT OF DR. CHALMERS W. SHERWIN, DEPUTY DIRECTOR, DEFENSE RESEARCH AND ENGINEERING (RESEARCH AND TECHNOLOGY), DEPARTMENT OF DEFENSE

Dr. SHERWIN. Thank you, Mr. Chairman. I appreciate the chance to be here. I will read Dr. Brown's prepared presentation, and then I will be glad to answer any questions that I feel I can answer.

I am pleased to be able to meet with you today and discuss the interaction between the Department of Defense and the National Science Foundation. These relationships are far too numerous to examine in their individual details. Therefore, I will attempt to explain them in general terms, and discuss their rationale.

Dr. Hornig has already described the top-level program and policy structure which has been rapidly developing in the executive branch during the past few years. Of course, these supply one kind of connection between NSF and DOD of which you are fully aware. I will say little more concerning these bodies other than that we in the Department of Defense believe them to serve a most useful purpose, as they regularly bring together those in Government research and de-

velopment at the policy level. Since it is also at this level of Government that major plans in research and development are considered, the mutual interaction in the Federal Council is leading to a much better understanding of the whole Government involvement in any large field of scientific activity.

The next set of relationships I will mention is that of direct interagency planning of activities between the Department of Defense and the National Science Foundation in major programs. A good example of this lies in the Antarctic research program in which our Department provides a major share of the logistics in meeting overall requirements of a national plan assembled under the direction of the National Science Foundation. In this large effort, Defense Department scientists also participate along with scientists of other Government agencies and the private sectors of our Nation. Our work thus becomes part of the overall coordinated effort under the NSF national office.

A very similar relationship exists in another program in which the National Science Foundation plays a central role—the International Year of the Quiet Sun. Since we have a number of interests concerned with meteorology, solar activity, ionospheric physics, geomagnetism, and aeronomy, we have quite a few of our scientific projects dovetailed into our total national effort in this program. Through these NSF coordinated program activities, we feel we have gained considerably in our ability to exchange data on some of the most peculiar and complex phenomena which we are studying. Scientific progress on global basis has been greatly aided by such massive ventures. In this field individual investigations have been plagued for decades by the puzzle of their tiny, inadequate supply of data, which was really much like one tiny piece of a giant jigsaw puzzle. Another large program in which we act under the coordination of NSF is the International Indian Ocean Expedition in which we are engaged in considerable oceanographic research.

Another set of relationships is developing between our agencies aimed at improving the coordination of our activities and mutual interests in small projects. Each of the military department units which are the major supporters within the Department of Defense of small projects (ONR, ARO, AFOSR), the research offices of the three military services, exchange status reports on their activity on small project proposals with each other and with the National Science Foundation, the National Aeronautics and Space Administration, and the Agency for International Development.

These status reports frequently lead to other more direct forms of coordination. It is not at all unusual for a program manager in the Department of Defense to refer a meritorious research proposal in which we see no particular relevance to the National Science Foundation for possible favorable action. We have never been in the position where we could afford to sponsor all research that might be scientifically interesting. In order to be constructive in assisting the growing numbers of talented scientists whose work does not fit our broad program objectives, we feel we now need to improve our referral system.

The present scheme is imperfect in that no one agency can ever be certain that they have made the best choice of the most relevant research

to their mission. Neither can they be certain that they have referred proposals to all of the agencies which might have an interest. In addition, there is an interesting overall statistic which is missing—the fraction of acceptable or desirable research proposals which never were accepted and sponsored. I feel certain that this latter information would be helpful to the NSF, to Dr. Hornig, and to the Congress.

A different kind of joint arrangement also exists, involving the mutual support of specific projects by the Department of Defense and the National Science Foundation. One of these is Stratoscope II, a high altitude balloon program in astronomy which involves both very basic research and the development of a high altitude, large payload balloon capability. This program is one shared between NSF, DOD and NASA. A second example is a joint radio-astronomy project at California Institute of Technology in which both the DOD and NSF have had strong interest.

These are the existing kinds of interaction between NSF and DOD. I believe there are some new mechanisms that will develop which will assist all Federal agencies to act more as a coordinated unit. One of these is certainly in the exchange of information on the detailed composition of our various research programs. We have two efforts now going which may serve as prototypes of better systems of exchanging this type of data. The first one relates to an agreement with NASA to exchange data in a common digital language on work programs in progress in the form of what is called a research and technology résumé. By this means we are already transferring data on all Department of Defense basic research projects into the data bank of the Science Information Exchange. More detailed data on all defense projects will be maintained in a central file within the Department of Defense. Perhaps this arrangement could profitably be adopted elsewhere in the Government.

A prototype experiment on data of this type has been carried out during the last 6 months in collaboration with NASA. This experiment is called Project ILSE (Interagency Life Sciences Supporting Space Research and Technology Exchange). It is aimed at using a computer file to produce an indexed list of life sciences projects so that effective coordination and balancing of programs can be attained. Although the experiment is not yet complete, we have found that we can get the necessary order in the information so that a group of specialist panels may now examine all of the projects in which they are each expert. The research and technology résumé system will permit this detailed coordination to be extended to all technical fields.

Mr. DADDARIO. Thank you, Dr. Sherwin.

Mr. Roush.

Mr. ROUSH. No questions.

Mr. DADDARIO. Mr. Waggonner.

Mr. WAGGONNER. We were discussing here this matter of coordination. Would the Department of Defense be willing to have some other agency in the Government be the coordinating agency, and subject itself to its decisions with regard to this research?

Dr. SHERWIN. At what level or to what size of project do you think this question applies?

Mr. WAGGONNER. At all.

Dr. SHERWIN. All projects. Let me state my own strong convictions in this regard, that the research programs and scientific and technology programs are a vital matter for all mission-oriented agencies, and their selection is generally strongly biased by their mission orientation, a fact which can be observed by the pattern of support which you will observe of the mission-oriented agencies with respect to the different fields and even in fields with respect to the various technical areas. They, therefore, will have a strong interest in supporting one area over another. If they had to get approval from a central agency for every program they supported, it would I think be a very cumbersome decision procedure.

The solution which I think would be more practical and is the one which we feel can be attained is to provide efficiently and easily by means of a digital reporting system an accurate description of everything that is going on. Under those conditions most adjustments of the modest scale programs—by modest I mean the smaller ones, below, say, a hundred thousand dollars a year size packages—can be readily made by interagency agreements without having literal authority or prior approval requirement by a superagency organization.

On the big programs, the large ones, the ones that involve, say, the very large accelerators, something like this, clearly the Government must provide some way or other some sort of centralization about who supports which project.

Mr. WAGGONNER. Is the new mechanism to which you referred a few moments earlier the one that you believe would work in this coordinating effort?

Dr. SHERWIN. Yes. If you look at the activities that go on in the various agencies, there are just thousands, probably at least 50,000, maybe a hundred thousand specific projects, research activities in basic research and applied research and technology being supported now by the Federal Government. Most of these have a close relationship only with a few others in the same field. A fast interchange of information of on-going work would permit people to relate these many things together efficiently. While the work is still in progress, permitting, therefore, mutual adjustments long before the work is completed.

Let me give you an example. I have mentioned ILSE, the program of interchange between NASA and DOD on life sciences. The last cycle of this coordination which went on last winter had in it nearly 4,000 what we call work units. The work unit is the natural unit into which packages of research are divided for local administration. It corresponds on the average to approximately one professional man-year of effort. It varies; it sometimes can be 10 or sometimes less, but on the average maybe 1 or 2.

In the case of the life sciences program there were 4,000, a little over one-half in defense and somewhat less than half in NASA. Out of these 4,000 work units describing ongoing work which were printed out and correlated on the computer, only six needed what you might call serious effort at coordination by the central committees. They were identified as having questionable relationship. I haven't heard what happened on those six. The thing that amazed me was that there was such a small number that were questioned by the joint

committees. There were 27 committees that looked at the entire program.

(The following additional information has been submitted by Dr. Sherwin:)

A detailed examination was made of the six pairs of apparently duplicatory project. Two pairs were found to be in unwarranted duplication, and one member of each was terminated. One pair was found to represent two different approaches to the same important and difficult problem and was justified. Three pairs were found to be nonduplicatory.

Dr. SHERWIN. I believe it was small because this ILSE program had been running for 3 years, and when they started to make up their fiscal year 1965 program 1 year ago they had a complete print-out of the entire program of both agencies in front of them for fiscal year 1964. As a result, each group had been in contact with every group that was working in its field. They had already had a series of meetings on a working level, and they had formulated a program such that very few things needed to come up for coordination by a central decision-making group. In the case of NASA and DOD we have a joint agency whose primary responsibility is to resolve these differences on a common basis. (The Aeronautics and Astronautics Coordinating Board.)

Mr. WAGGONNER. Is DOD expending any moneys to aid science education?

Dr. SHERWIN. Not directly. We support about $130 million which goes into universities in research programs related to the educational process. These are not the big contract centers but the research programs that are on the campus with the students, and in almost all of these graduate education in research is supported. That is essentially the degree to which we are involved.

Mr. WAGGONNER. Are you giving any money for fellowship grants to individuals?

Dr. SHERWIN. Not to my knowledge.

Mr. WAGGONNER. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. For the past several years you have been interested in the project which might be known as "Where Do Good Ideas Start?"; that is, from where do key advances originate which come to the Defense Department as major system changes. Are there any conclusions about this project which you would like to mention at this time?

Dr. SHERWIN. Yes; I would like to make a couple of comments on it. It has been of great interest on my part for 2 years now to ask the question, Where did the payoff actually come to the Defense Department from our investment in research and technology? Has it been substantial? Is there any evidence that different ways of investing this money over the past 20 years have paid off more to Defense than others?

We have finally started on a serious effort. A pilot study was done last summer with a group of people in my office and from the military services under the leadership of one of the members of my staff, Dr. Lawton Hartman. Also we have a contract study with a contractor which has just now been completed. Both studies seek to identify the key advances in research and technology which in fact have turned out to be useful or vital to defense systems. We track the key events

down and find out how they got born, how they got generated, how they got supported, and examine the management environment in which they emerged. We entered into this with the expectation that we would see a pattern, and clearly there is a pattern. One of the most remarkable things which I didn't expect this because I am biased the other way, is that most of the key advances which turned out to be useful were closely associated with people that actually had systems equipment to design and build. I had expected that most key advances would come from people who were sitting around with a lot of equipment, in a relaxed atmosphere, thinking about what people ought to want. Also, we found that almost all of the key advances were initially financed by locally controlled resources. I suspected this would be the case since I had personal knowledge of a number of such events. Thus, practically nothing that is really hot is ever "pushed down from the top," it is rather almost invariably recognized by local people faced with a real problem, initiated by them without the benefit of any paper work and financed by hook or crook (if necessary) by some sort of locally controlled resources.

Mr. VIVIAN. What do you mean by locally controlled resources?

Dr. SHERWIN. It is company money, or is bootlegged money on the part of a laboratory, or it is money which is given under general direction which the local management can legally allocate without prior approval up the line. In other words, it is really locally controlled, and we found that practically all of the advances were initially financed under those conditions. It gives flexibility to the local management.

Much of our current contractual support is not that way. In many instances it is pretty constrained. But these inventions were not supported initially that way. They may have received specific support later when it got expensive.

Mr. VIVIAN. Do you think they received local support because it was tough to get higher support, or because it was a very attractive proposition that no one wanted to disclose?

Dr. SHERWIN. I think it was because of the ponderous delay in seeking higher support. In one case they did make an application and a year later they did get support.

I might say we are just launching a new effort to make a very careful study of this on a larger scale. The Defense Department has made the biggest investment in research and applied research of any organization in the world, certainly in the United States. We have invested about $10 billion in research and technology since 1946. We have an inventory of weapons that is worth the order of $100 billion.

Now, in the weapons that exist today there is buried an enormous number of technological advances most of which we have paid for directly or indirectly in the last 20 years. We want to find out what those key advances are and to what degree the improved performance of the weapons is due to them. We then expect to compare this net improvement in our weapons systems for the defense of the country with the actual investment that we put in—about $10 billion. I expect a very large payoff has occurred. Practically no weapon system is ever undertaken that does not promise to have at least double the cost effectiveness of its predecessor, if such existed. Most of them are considerably higher than this. Take a ballistic missile, for example,

if you increase its accuracy by two without increasing its cost it is four times as cost effective against hard targets. This very easily happens by a very modest change in guidance accuracy.

If we designed our systems today with the science technology of 1950, I suspect that, rich as we are, we could not afford them. I believe that if we make our study carefully, we will find that our investment in research and technology has been the best investment for defense that the country has ever made. If it can be calculated, I think the payoff will turn out to be absolutely enormous. We hope to get very solid data on this within the year.

Mr. VIVIAN. You have indicated that these came out of what you call mission objectives, in other words, certain goals. Is this somewhat in contradistinction, for example, to some of the endeavors of NSF which are general support endeavors? In addition, you indicated that these were under what you mentioned as free money, and I do not mean in the context of being inexpensive, but money that you were able to move about in areas that were not necessarily agreed to in the beginning. Has this led to any policy changes in contracting on the part of DOD, or do you anticipate that it will?

Dr. SHERWIN. Mission objectives are clearly vital in directing the effort in technology. I think you have to get the technical people exposed to the problem in a real way, and in addition you have to provide them with flexibly controlled funds so they can work on problems without waiting. Also, they must have a solid base of scientific knowledge which they can apply to the problem. Thus there are three things that are all necessary to produce utilized technology.

We feel that our contracting policy for our early development and our applied research functions could be profitably changed in the light of the results of these studies. However, we would like to wait a year and collect and study more than the 100-odd key events so far identified. We need a much larger number, probably a thousand or so, covering a bigger fraction of the weapons inventory, before making any serious effort to shift the policy. For 20 years the policy has been what I call a seat-of-the-pants policy—people simply generate personal opinions on how one ought to administer and how one ought to allocate resources. The trouble with the scientific community is that they are only really interested in how to spend the next billion dollars, not in what happened to the last billion. They just aren't interested in lessons from the past.

But it is terribly important today. I think that looking backward into the past and seeing what has really happened is absolutely necessary, and that the Defense Department is a perfect place to do it. We have the biggest, longest, and most varied history of investment, and we have a measurable output. Even though I believe the payoff has been very great, I think we can learn a great deal about how to use our resources better.

Mr. VIVIAN. You would think that some of the ideas may well apply to NASA; I am not saying they should, but they might.

Dr. SHERWIN. I am sure they would. It will be a long time before they will have the data base for such studies that we already possess.

Mr. VIVIAN. Would they apply to research on water pollution and desalinization?

Dr. SHERWIN. I think there would be general application to any goal-oriented activity which uses science and technology. The substantial and long history of investment by the Defense Department is important because it takes 20 or more years of history to perceive the full consequences. It takes 5 to 10 years for even applied research to come out at the end of the pipe, it takes 10 to 20 years or more for basic research to come out at the end of the pipe.

Incidentally, the payoff time is another thing we carefully observe; that is, when were the inventions made with respect to their applications? We have already picked up a number of key research events, as contrasted to applied research events, which are vital to national defense which have occurred in the interval since 1946.

Mr. VIVIAN. Do the provisions which exist in many defense contracts by which a certain percentage is left to the contractor for his own research efforts in any way in conflict with the work you are now undertaking?

Dr. SHERWIN. This principle is called the armed services procurement regulation allowance for independent contractor research. This has been going on for many years, and, judging by the output of useful results, is a good thing. Many of the contributions we identified came out of this fund.

Mr. VIVIAN. Can you identify them directly for the record?

Dr. SHERWIN. Yes. People usually remember what kind of company money was used. Some came from profits, and some came from the funds just mentioned. A fair amount came from people bootlegging funds not specifically allocated to such functions because they believed in an idea.

Mr. DADDARIO. What percentage of the contract do you allow an industry to use for this independently motivated research?

Dr. SHERWIN. It varies with industry and the organization, of course, and somewhat with history. I believe the numbers run around 1 percent or maybe one and a half, something like this, under the conditions where it is allowable against production sales. It is a fair amount of money.

Mr. DADDARIO. I imagine on occasion it runs higher than one and a half percent. We would appreciate it if you would get that for us. While you are getting that information, I think it might be helpful if you could give us the lowest and the highest percentages involved.

Dr. SHERWIN. Right; we will be glad to give you some examples.

(The information requested is as follows:)

Analysis—Independent Contractor Research (covered by advance agreement)

		Fiscal year 1963
Average allowance (in a percent of total sales)	percent	0.91
Lowest allowance (to any contractor)	do	.4
Highest allowance (to any contractor)	do	4.5
Total cost of contractor independent research and development program (as proposed by contractors)	million	$381.6
Total amount of proposed cost allocable to Government (determined by negotiation)	million	[1] $194.2
Contractor total sales (for this contractor group)	do	$21,315.0

[1] Most of this $194 million was applied research and exploratory development; only 10 percent or less was estimated to be basic research as defined by National Science Foundation.

Mr. VIVIAN. I will come back to that in just a moment. First, I would like to point out that the DOD procurement is on the order of $50 billion. I realize that manpower is a factor; however, $50 billion multiplied by 1 percent, for example, would be a half billion. That would be a significant fraction of the $1.7 billion estimated for basic research. In other words, the numbers under this program are not small.

Mr. WAGGONNER. That is not possible because $15 billion is in salaries.

Mr. VIVIAN. I am saying I have been very cautious.

Dr. SHERWIN. Our procurement is closer to $20 billion per year, and of the actual equipment to which these regulations apply it may be less than that. (In 1963, as the preceeding table shows, this amount was $21.3 billion.)

Mr. VIVIAN. This would drop it down to about $150 million.

Dr. SHERWIN. Still it is a rather substantial amount of money. I might add it is used for other things than research. It is used for proposal preparation and other necessary internal costs of doing business; so, it all doesn't get into research. Even then it mostly gets into applied research because this is where they get the shortest term and the highest probability of payoff.

Mr. VIVIAN. Perhaps the amount I mentioned was high.

If there are no objections, I have several other questions.

Mr. DADDARIO. You may continue. You are doing fine.

Mr. VIVIAN. You indicated some comments on the subject of interagency transfers on page 3. You comment, "It is not unusual for a program manager in DOD to refer a meritorious proposal to NSF." Would you have any idea what percentage of proposals this would apply to?

Dr. SHERWIN. No; I don't. We could find out if you are interested.

Mr. VIVIAN. Five percent, 25 percent?

Dr. SHERWIN. I would guess it is closer to 20 than 5, but I could inquire and get some estimates. It is not something that we keep systematic records on.

At present and for several years in the past there has been complete exchange of information concerning research proposals on a monthly written basis among the following Federal agencies: DOD, AEC, NSF, NIH, AID, NASA, ARPA. We consider this coordination to be very effective. We further expect centralized collation of all research proposal information to be accomplished in the near future, as mentioned in my prepared statement, through the Science Information Exchange.

Mr. VIVIAN. Why would you refer the proposals to NSF? Would it be because of relevance of the work or funds involved?

Dr. SHERWIN. It might be both. In the DOD agencies the relevance of the program to the general interest of the Defense Department is an important weighting factor. If you notice the ways we are supporting research, about 70 percent of all the engineering science in the universities is supported by the Defense Department. This is not an accident. The reason is simply that we have a strong interest in the engineering sciences. We are strong in chemistry and solid state and optical physics; we are are low on the biological sciences, where

the National Institutes of Health are high. So, over a period of time we have gradually focused our efforts on those programs which are most relevant to the Defense Department. Our budgets tend to get big in electronics. When we get a project in in some special area of chemistry, for example, and we can't touch it because of our budget limitations, we refer it to the NSF or elsewhere.

Mr. VIVIAN. Are there established guidelines printed and promulgated to guide your contract administrators and unit heads in what they should refer to other agencies under certain conditions?

Dr. SHERWIN. I believe not.

Mr. VIVIAN. Would you construe such guidelines as being undesirable or not?

Dr. SHERWIN. I think they are probably not necessary. Each of the three agencies has a very well thought through general plan of their research program for the next few years, and they compare the proposals coming in with where they are trying to go, and then they pick the things they feel are most relevant or most exciting or the best combination, and they refer the others to the other agencies automatically. I think that function is being done quite well.

One thing I think would help, as I mentioned in the prepared statement, would be a more systematic system in which all proposals are filed in the Science Information Exchange. Thus every agency would more easily know who is receiving proposals, but it would then be possible to keep systematic track of what happens to them. At present, although they are efficiently referred from one agency to another, no one keeps a record of the overall picture.

Mr. VIVIAN. There are no guidelines which have been promulgated; there is no criterion which one follows on an established basis?

Dr. SHERWIN. Nothing written down, except, of course, the long-range plans and priorities based on relevance of each military department.

Mr. VIVIAN. What do you construe as the principal purpose of the research carried on by DOD? I do not mean research, for example, in supersonic aerodynamics, which very clearly relates to the various aircraft with which you deal, or, say, with certain types of research in electronics, which may be almost totally military in character. I refer to research in a field such as mathematics. I know DOD has done this in the past. Do you still carry on any research in mathematics today?

Dr. SHERWIN. Yes, quite a bit. We are one of the strongest supporters.

Mr. VIVIAN. What would you construe that that would do for the Defense Department that wouldn't be done equally well under NSF?

Dr. SHERWIN. As an example, I was just reading the Office of Aerospace Research description of their mathematical interest. They were discussing the importance of a particular class of differential equations which are related generally to military problems—control problems, and aerodynamics problems—to which they were giving priority. Also, we have heavily invested in the special areas of mathematics associated with the programing and use of digital computers.

Each of the three military contracting organizations has a plan which they call their research or their technological forecast or their guidelines for research, which indicate the areas of primary interest.

I could provide you with a set of each of these from each Department to give you an idea how they determine their program.

Mr. VIVIAN. Going back to the subject of mathematics again, I can construe several valid purposes for research in the agencies. Certainly one of them is to develop a field of science which is not necessarily unique but extremely important to that particular mission agency and which may have very little relevance to the other agencies, or for other purposes. A second purpose, I would say, would be the education of the staff of the agency. Certainly you must maintain your own staffs at a high level of understanding, and they can gain some of this education by having either in-house research or by contractor research which is delivered to them and which they absorb by merely being exposed to it. This is all right. The same thing is true of the contractors. As a practical fact, you can have no useful contractors without giving them work experience in the field in which you expect further work. From my point of view, this is a much bigger factor with respect to most development contracts than many people realize. However, I really don't see how the subject, for example, of research in mathematics fits very well into either of these categories. It would seem to me that this could be done very well, for example, by NSF.

Dr. SHERWIN. I am sure that parts of it could be. I believe, however, that I can identify certain areas of mathematics which meet your first criteria, namely, that they are extremely relevant to the problems that the Defense Department has and need encouragement by offering support.

As an example, the mathematics of linear programing which we have heavily supported might conceivably have received relatively little support emphasis from a pure-science-oriented organization. It has produced a manifold payoff for Defense. Let me cite a single specific instance. The Defense Fuel Supply Office annually picks successful bidders for the supply of over 200 million worth of jet fuels. One of the significant economic factors that had never been adequately taken into account was fuel transportation costs to various depots. The problem of minimizing total cost to the Government is a complicated one that must take this geographical factor and other cost factors into account. It turns out to be reducible to a linear programing problem. By application of this mathematical technique, with the help of modern high-speed computers, it has been possible to effect an estimated annual savings of $4 million. This is only one of many examples of the application of this versatile mathematical method. It even has direct military tactical applicability to such problems as optimum schemes of multiple bomb delivery by manned aircraft.

Another area of fundamental mathematics I suspect would receive less emphasis from a pure-science-oriented organization than it deserves in terms ultimate payoff to the taxpayer is that underlying the prediction of equipment reliability and assurance, statistical quality control, and process planning.

I hesitate to guess how many millions of dollars have been saved through the application, for example, of sequential sampling techniques in equipment evaluation and quality control. These techniques, going back originally to wartime work of the mathematician A. Wald, were early recognized for their defense significance and were used in

World War II as one of this country's secret weapons. Subsequent Defense-supported fundamental statistical research growing out of the early work has led to entirely new systems of inspection sampling, implemented by military standard 105 and its subsequent revisions, which now benefit also our allies in a NATO version.

About high-speed electronic computers, which have both drawn upon and contributed to fundamental mathematics, I need say very little. I am sure you are well aware that these devices, which already are having such an impact on our lives that they may be said to be ushering in the age of automation, were in their inception wholly supported, and are still today mostly supported, by Department of Defense fund sources. Not only are we still the primary source of support for computer technology and design, we are also the primary source of support for new and radically improved programing methods, including multiple access and new machine languages such as Militran.

Another area of mathematics receiving our strong support is nonlinear systems and adaptive control theory.

Indeed, our concern for relevance is so great that we turn down approximately 60 percent of the formal proposals made to us, and discourage many more in the state of informal negotiation.

Mr. VIVIAN. How does a contract administrator in DOD decide whether mathematics project "X" belongs in DOD or in one of the other agencies? I don't care which agency right now.

Dr. SHERWIN. Each of the agencies receives, first of all, comments by peers on the quality of a program for scientific quality. Then, in the case of the Army, these proposals are sent around to the Army in-house laboratories for evaluation comment on all proposals that come in. Then, they look at their overall plan for emphasis and growth in various technical fields. Combining those together, they make up their decision about support. So, if, for example, a university has a project in a mathematical area which looks like it is interesting or useful to one of the Army laboratory people, or in one of their projects or a project which they know about, which they often do, then, they would presumably get support. The other services do not send it out to the in-house laboratories, but they do examine the program in terms of the overall plans which I mentioned earlier, and which bias their decisions. So, there is a strong tendency toward relevance. Also, in each of the three contracting agencies there has grown up in the past several years a systematic effort to try to relate their research programs to their mission activities. They have seminars, discussions, and meetings, visits to laboratories, and so forth, trying to determine where are the areas of science which are most related and need the greatest support. There is a growing interest and concern with this problem, and mechanisms are being set up to improve the coupling between research and application. We must be cautious and not extend the relevance principle too far or too consistently, for we need diversity of support for new ideas and, if only one outfit can support a given class of ideas, then everything hinges on its wisdom.

Mr. VIVIAN. I should comment that people in the scientific community do not wish to have sole-source support. They much prefer to have several different agencies, so if there are human blockades, as there always are in every agency—perhaps a person who has a certain dislike for certain ideas—these people do not stop all worth-

while activity in that area. I am not objecting to this. I am trying to find out how you adjust the total volume. I gather the answer is that the machinery of adjustment is still somewhat uncertain.

I would like to come back to this subject of comments by peers. I believe NSF has a system by which proposals are evaluated by advisory groups of individuals in the same area of technology who are considered to be technically peers of the submitter. Do all the agencies of DOD have organized procedure for evaluation by peers of all research contracts?

Dr. SHERWIN. No. In fact, we support universities at a total level of about $400 million a year. This accounts for contract research centers, applied research and basic research, the general program type and the specific project type. Of this, $300 million is not involved in peer evaluation. This covers our contract centers, our applied research programs, and our general programs. Thus, three-quarters does not utilize peer evaluation.

Peer evaluation is involved in about $100 million, mostly specific projects. The peers are a rotating group in order to provide diversity. They give their individual comments and evaluations. In the case of the Army, the proposals go to the in-house laboratories for comment. In the case of the other military departments, they discuss them among themselves in the light of their overall plan. Thus, although the DOD staff uses peer evaluations, in about one-quarter of their total university program, they are only a part of the decisionmaking process.

Mr. VIVIAN. Are the memberships of these peer groups identified; that is to say, is it generally known in the industry who is the evaluating group?

Dr. SHERWIN. No, it is not. There is a large panel of people who are called upon, and different groups are called on for different cases. In many cases the Government evaluators in the central agency do not have the names of the peer evaluators involved in specific evaluations. They just see the results. It is a fairly objective method.

Mr. VIVIAN. I have a comment to make on the subject of ILSE. Is this computer so organized that it can be distributed to the public? In other words, is it available to the general scientific public?

Dr. SHERWIN. It can be done.

Mr. VIVIAN. Is there harm in so doing?

Dr. SHERWIN. Part of the work is classified, and that part of it would be deleted; otherwise, it could be done.

Mr. VIVIAN. But some of that is available to contractors who already have volumes of scientific classified information?

Dr. SHERWIN. Yes.

Mr. DADDARIO. Do I understand you correctly, that it can be done and is being done, or it can be done and is not being done?

Dr. SHERWIN. I must say I am not certain how wide the distribution has been. It is going, I know, to selected organizations and individuals that are active now in the field of life sciences being supported by NASA and DOD. It is not now going to a broader group. It is inexpensive to print out a format which would be suitable for public distribution and make it available to the public.

I am not sure that it would really be necessary. I think it is more important that the scientific community which is most directly involved has access to it for purposes of management and decision-making, and that is possible.

Mr. DADDARIO. And is being done?

Dr. SHERWIN. It is now distributed in a complete form to nongovernmental consultants associated with either the NASA or DOD life sciences programs. We are also giving the unclassified material to the Science and Information Exchange, which is widely accessible.

Mr. VIVIAN. I think that is something, Mr. Chairman, which we might ask to have looked into further? Is this desirable or advantageous to the many people who are putting in these proposals. In a sense, the major supporter of the life sciences is NIH. Is it involved in any way?

Dr. SHERWIN. Not at the moment. This is a DOD–NASA interchange. DOD and NASA have proposed to all the agencies in the Government that they join in a common digital language system which would permit an interchange on the basis of the R. & T. resume system. NIH has not yet joined, but we have had several discussions with them.

Mr. VIVIAN. Do they receive print-outs?

Dr. SHERWIN. We give print-outs to individuals in NIH, and are willing to transmit official copies if they request them. Also, we now give all the unclassified data to the Science and Information Exchange which NIH uses a great deal.

Mr. VIVIAN. Presumably, under research contracts virtually all the funds that are awarded are used for research purposes, including overhead requirements, and so forth. Under research and development contracts, which are often labeled development contracts to generate a specific end item, what percentage of them normally produce what is called research effort? It must be a sizable fraction.

Dr. SHERWIN. It is, and it is very hard to estimate. Indeed one of the primary sources of funding of the key advances that we have observed thus far did come from development contract money which was allocable by local agreement to applied research and even research problems that came up in the process of development. Research, particularly applied research, tends to get born where it is needed and where people get excited about it, and where there is a sense of urgency. At the moment we do not have a systematic method of sorting out from our development programs that part which is going into research. We feel that the R. & T. résumé system is well suited to this purpose since it is brief and flexible. You can take bits and pieces of programs which have research content, put them into the standard digital format and then relate it to all similar work wherever else it is being done.

Mr. VIVIAN. What number of dollars goes into development contracts per year?

Dr. SHERWIN. The R. & D. budget in Defense is about \$6½ billion, and of that only about \$1½ billion is in research and technology or exploratory development. About \$0.9 billion goes into

advanced development and $1.3 billion goes into engineering development.

Mr. VIVIAN. Of the development contracts, what would you estimate might be labeled as research by some reasonable standards?

Dr. SHERWIN. In the past or in the future? Let me speak first about the future. Because there has been a very important shift in policy in Defense in which engineering development requires, whereever possible, fixed prices and predictable performance. The new rules are that you must have the technology and the scientific facts well in hand before starting. Engineering development is our major category, over $1.3 billion a year. Under these conditions we will expect very little research and applied research to be done. It shouldn't be necessary at that stage. However, we do expect a substantial amount to be done in advanced development. This category is running at a little under $1 billion a year. My opinion is that it would be entirely reasonable to have 10 or even 20 percent of the money in the advanced development stage available for closely related research or applied research. This is just the area in which our studies have indicated applied research is most effectively done—when you are in the early stages of a development program when you are not yet aiming at a fixed time deadline, when you are not committed to production, and when you are trying to show feasibility of a new concept.

Mr. VIVIAN. I concur with your comments. That would suggest an additional $200 million to research.

Dr. SHERWIN. Part of that money could be obtained by merely allocating part of our exploratory development funds for this use. Part could be obtained from the larger expected savings in engineering development. Thus, it would not necessarily require an increase in the total R. D. T. & E. funds.

Mr. VIVIAN. I have seen a series of statistics earlier which left me with the conclusion that it did not reflect very accurately to my knowledge the situation as it exists. I think that once certain labels were applied to these funds, from then on they go through the tabulations with no further inspection.

Let me come down to procurement funds. Under procurement funds presumably relatively little research was done, although there have been famous contracts in which research was done in the past. How about the future?

Dr. SHERWIN. One of the sources of overruns is the fact that this has occurred, often from necessity. Presumably, in the future this would happen very infrequently because the procurement would be committed against a fixed price contract and based upon on-the-shelf technology. I am not sure that some technology work won't be necessary, for no prediction is perfect, and unforseen problems will arise.

Mr. VIVIAN. I have two other questions. The first one is on the geographic distribution of research funds. It is my understanding that there is no policy in force within the Defense Department relevant to geographic distribution.

Dr. SHERWIN. Right.

Mr. VIVIAN. At no time is a contract administrator given any instructions to consider geographic distribution in his efforts?

Dr. SHERWIN. I believe that is correct.

Mr. VIVIAN. Would you estimate that any significant fraction of the DOD contract awards are given at a time when the selection between the top several contractors is at best somewhat murky or rather difficult to decide?

Dr. SHERWIN. I am sure it often happens.

Mr. VIVIAN. Like quite frequently, for example?

Dr. SHERWIN. Yes; it probably does.

Mr. VIVIAN. Under these conditions when the technical criteria and the administrative criteria and the management criteria are at best hard to differentiate, to put it mildly, do you think the geographic consideration is totally inappropriate, or would you rather not answer that question?

Dr. SHERWIN. I certainly feel that I should not speak for the Defense Department on this important policy issue.

Mr. WAGGONNER. Could I interrupt there?

Mr. DADDARIO. Mr. Waggonner.

Mr. WAGGONNER. It is safe to say that the Defense Department is concerned with maintaining a certain amount of potential productive capacity the Nation over for times of emergency, isn't it?

Dr. SHERWIN. Yes. They have a number of standby plants, all of them maintained for this purpose.

Mr. VIVIAN. They do not maintain standby research and development plants that I know of.

Mr. WAGGONNER. Of course, they don't have a lot of in-house capability there.

Dr. SHERWIN. We have quite a bit in-house. We have over 30,000 scientists and engineers in the Defense Department. A great fraction of them, 20,000, are in laboratories and technical organizations distributed all over the country, although largely on the east and west coasts.

Mr. VIVIAN. And Dayton?

Dr. SHERWIN. Dayton, Ohio, being the largest exception.

Mr. VIVIAN. There are a very large number of contracts that usually come down to the wire in which the person making the contract decision wished there were greater differentiation between the contractees so he could make a better decision. Under these considerations geographic distribution is a rational consideration. I think this is done sometimes by the Defense Department, but I believe it is done without any guiding principles where someone can be pinned down on it. This is where my concern lies. I do not believe there is any policy to guide a contract administrator whereby if he followed it, he would be considered as acting in the Government's interest, or where if he violated it, he would be considered as acting against the Government's interest. The lack of policy is what concerns me.

Now, my last question. The quality and quantity of scientific manpower left much to be desired in some years past, and we have put forward an effort during the past decade to train and develop more talent. This was referred to by the previous speaker a few moments ago, particularly in reference to Dick Bolt's model.

Has DOD generated anything which you would call equivalent to a mathematical model for predicting its needs in technical manpower in various levels of quantity and quality which would in any way relate, for example, to the one referred to a few moments ago?

Dr. SHERWIN. I believe there are no mathematical analyses like this. Dick Bolt's article, which I scanned when I saw it, is the first of this type to my knowledge. We have studies and analyses and plans, but they are currently made without mathematical models.

Mr. VIVIAN. My estimate of the forecast information available from places like the Library Congress, which is, of course, a collection agency as well as a generating agency, is that the prediction information available on which to base further educational programs is, to put it mildly, exceedingly qualitative. It could be that we need fewer, or more, or the same number, but we will never know it from anything that is available to us today. While they may be wrong, they may also be right. I would appreciate it if there is any information in DOD which leads to a wise understanding of what the future needs will be.

Dr. SHERWIN. I will inquire to see if there is any new type of work going on that would have the kind of an approach that you mentioned. (Note for record: I have inquired and found there is none.)

Mr. DADDARIO. Just following that a bit, does DOD look to the National Science Foundation as the source from which it can derive, or should derive, or does derive, its scientific and engineering manpower information?

Dr. SHERWIN. Their reports are the national standard of information in this area. We use them to the degree that they are related. So, we use them all the time.

Mr. DADDARIO. You see this as being an important function of the National Science Foundation in respect to your work?

Dr. SHERWIN. Oh, indeed, it is. Also, the ability to make better predictions and to make more accurate up-to-date evaluations of the numbers of people is greatly to our interest. We would be very much in favor of seeing an even better job than they are doing now. They are doing a very valuable job. I listened to Dr. Wolfle's testimony, and would agree that we could easily use better data, and we would find it very valuable.

Mr. DADDARIO. You talk about better and more up-to-date data, and you agree with Dr. Wolfle in that regard. Do you have any examples of information that you now need, and which NSF could supply, but which is not available to you? Is there a vacuum in this field?

Dr. SHERWIN. I am not familiar with it in detail, but I could give you one example of an answer which we are interested in. We would be interested in knowing with respect to all the Defense grants given to universities and all the graduate students thereby supported how many students later contributed to the Defense Department programs. This kind of questioning could come out of a manpower survey that had adequate data base. It could be pulled out automatically if they had the information there. We could trace these people back, determine their support, and determine the way in

which we have benefited by our indirect support to graduate education.

Another interesting point. When people do graduate work they tend to have one great fault, or perhaps a virtue; they very often tend to continue to be interested in the same field. Thus if we interest people in, say, optical physics because we support it and because it is unusually important to Defense, we tend to produce people that would like to work in optical physics. We can hire them, therefore with relative ease to do work either for contractors or in the Government laboratories in optics programs. However, a student trained in high energy physics generally wants to do high energy physics and not optical physics. They could easily enter optical physics as far as their basic training is concerned, but their motivation is weak. Thus, the type of DOD support is biasing the interests of the graduate students toward our interests. In this manner, an emphasis on relevance may have very interesting extra consequences. An agency's interest and in heavy support of a given area tends to perpetuate the production of people interested in that area. The degree to which this has happened could be determined from adequate manpower records.

Mr. DADDARIO. What you are saying is that the information would be helpful so that you would know what manpower is available. In addition, if you added to that a label to show what contribution you made to getting them into this stream of activity, it would support the programs you now have, and thereby serve a double purpose.

Dr. SHERWIN. Suppose we could prove that the people we educated, so to speak, by indirect support of their thesis turned out to be an unusually high fraction of the people working on defense programs. This would seem to me to be an excellent argument for the mission-oriented agencies carrying on research in the universities. We do not have any evidence of it now. It might be positive or negative. I suspect it might be positive. The facts could only be obtained by a careful survey.

Mr. DADDARIO. Could we label all these people as DOD, NIH, or NASA?

Dr. SHERWIN. You could trace their history and determine the way it ended up, the way their careers were directed in the support of various Government mission activities or other activities. The ability to trace people and their activities in areas of interest to defense would be very useful. Incidentally, this is expected to be one of the consequences of the R. & T. résumé system. It breaks down the activities that are going on in such detail and gives the name of the principal investigator actually doing the work and the secondary one. Since, on the average, the work unit is so small, in most cases this is the whole staff on the work unit being reported. With our new digital historical files, we can trace back and find out where people worked, what contribution they made, what kinds of fields they were in.

If this were a standard Government-wide reporting system, then we could find out wherever people supported the Government, and in what way. This would take time, for the records must be built up. Five years from now we could play back the history of how people participated in the Government in the last 5 years.

Mr. DADDARIO. You are talking about an information system which would be so complete that it would provide all of the information you need, and the more information the better.

Dr. SHERWIN. You have to be careful about collecting information that won't be useful. If the information has enough detail to give an accurate breakdown in terms of technical fields, then the same information will also give very naturally very useful data on manpower inventory and flow.

I might add if for the last 10 or 20 years we had the records that the R. & T. résumé system will give us, we would be able to reconstruct the origins of the key contributions of research and technology to defense with much greater ease than is now possible.

Mr. DADDARIO. Do you see the National Science Foundation as being the agency under which this data could be assembled for assimilation to all the other agencies?

Dr. SHERWIN. The beautiful thing about the research and technology résumé system is it is a digital system. It has a common set of codes and definitions and therefore it can be stored and handled anywhere in the Government, permitting complete economical and almost instant interchange. There is no need for a central file. You can interrogate 15 agencies against the same set of data and bring together any information you want. If they speak the same language, the same digital meanings to all the words, and they are made against a common set of definitions and codes, then any agency can assemble and process any data it wants. It makes a very flexible tool. It can provide centralized knowledge but avoids the centralization of control in processing.

Mr. DADDARIO. Including industries?

Dr. SHERWIN. Including industries, providing we meet the requirements of security and proprietary information.

Mr. VIVIAN. If you have 30 seconds, Mr. Chairman, I would like to interject a comment. I have known Chalmers Sherwin for well over a decade. I think he is a very able person, exceptionally so, and the public is to be complimented for having gotten such an able person on its staff. I apologize for using your time, but I did want to take advantage of this opportunity.

Mr. DADDARIO. I am pleased you have.

You can tell Dr. Brown if he is not careful and sends you around too much, we might be asking for you in the first instance.

Dr. Sherwin, I am sure we will have a whole series of questions to send to you, and I hope you will be able to answer them for the record.[1] We cannot cover all the points that we would like to in the time available.

I want to thank you for your appearance.

This committee will adjourn until 11 o'clock next Tuesday at this same place.

(Whereupon, at 12:15 p.m., the meeting was adjourned to reconvene at 11 a.m., Tuesday, July 6, 1965.)

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, JULY 6, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m. in room 2325, Rayburn House Office Building, Washington, D.C., the Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This committee will come to order.

Our witness this morning is our distinguished Chairman of the U.S. Atomic Energy Commission, Dr. Glenn T. Seaborg. Doctor, would you proceed, please.

STATEMENT OF DR. GLENN T. SEABORG, CHAIRMAN, U.S. ATOMIC ENERGY COMMISSION; ACCOMPANIED BY DR. GEORGE KAVANAGH, DEPUTY ASSISTANT GENERAL MANAGER FOR RESEARCH AND DEVELOPMENT, AEC; DR. JACK VANDERRYN, TECHNICAL ADVISER TO THE ASSISTANT GENERAL MANAGER FOR RESEARCH AND DEVELOPMENT, AEC; AND GEORGE W. COURTNEY, JR., ASSISTANT TO DIRECTOR FOR PLANS AND POLICY, DIVISION OF NUCLEAR EDUCATION AND TRAINING, AEC

Dr. Seaborg. Mr. Chairman, members of the subcommittee, it is a pleasure to appear before you this morning. I am flanked here by Dr. George Kavanagh on my left, Deputy Assistant General Manager for Research and Development for the Atomic Energy Commission, and Dr. Jack Vanderryn, Technical Adviser to the Assistant General Manager for Research and Development.

Mr. Daddario. We welcome both of you gentlemen.

Dr. Seaborg. I am very pleased to be here today to tell you about the relationships between the Atomic Energy Commission and the National Science Foundation. The Foundation's activities have a significant effect on the well-being of science, technology, and education in the United States. This, in turn, is important to the successful conduct of the Atomic Energy Commission's programs. Further, as a scientist and an educator, I have a very strong personal interest in the activities and programs of the National Science Foundation. Therefore in addition to discussing with you the specific relationships of the AEC to the NSF, I would also like to comment more generally on the programs of the Foundation.

51-204—65—vol. 1——14

Basic Research

The National Science Foundation is charged with "the support of basic scientific research * * * to strengthen scientific research potential in the mathematical, physical * * * and other sciences * * *." This NSF support is without regard to eventual usage or application of the results. The mission-oriented agencies such as the Atomic Energy Commission specifically require advancement of knowledge in generalized but nevertheless somewhat more restricted areas of science and technology. As is the case with the AEC, proposals for research are funded by NSF on the basis of scientific merit. Because such funds are limited, only the highest quality proposals are supported by each agency and many meritorious requests must be rejected.

The future development of knowledge in areas of science not supported by a mission-oriented agency may well be of prime interest to that agency. Nevertheless, these agencies must place their major emphasis in areas of recognized need. When a "breakthrough" occurs in other areas, then the mission-oriented agency steps in to give the required emphasis. A recent example of this, concerning the AEC, was the study of superconductivity which might have appeared to have no application in its program. With the finding of magnetically hard superconductors and potential application in producing magnetic fields for use in controlled thermonuclear and high energy physics investigations, became immediately evident and our involvement in the field resulted. Thus, the mission-oriented agencies require strong national support of non-mission-oriented research. I can also cite an important example which illustrates the unexpected and broad benefits which can result from mission-oriented basic research.

In 1962 scientists working at our Argonne National Laboratory, following a lead from research results obtained by Prof. Neil Bartlett at the University of British Columbia, discovered that xenon, a so-called inert or unreactive element, could combine simply with fluorine. This has opened up a whole new field for both experimentalists and theorists. The work grew out of AEC's interest in the chemistry of fluorine and of the fission product gases such as xenon.

These two examples illustrate my contention that it is important to the continued strength of science in this country for both NSF and the mission-oriented agencies to continue their vigorous support of basic research. The emphasis at NSF should be on support of broad-based university research, whereas the AEC will continue to use both its own laboratories and the universities, as appropriate.

The AEC, like the NSF, makes extensive use of the scientific community in reaching decisions on supporting unsolicited proposals for basic research in the physical and life sciences. After first determining that the subject of the proposal is of interest to the AEC, an average of three scientific reviews in depth are requested of outside scientists known by our scientific staff to be working in or knowledgeable of the subject in question. That is, the proposing scientist's project is judged by his peers and we are assured of a continuing high quality in the projects we support. Final decisions

on acceptance of a proposal are made by the AEC staff taking into account the opinions and recommendations of the outside reviewers and our degree of interest in the subject matter of the research.

AEC–NSF Relationships

COORDINATION OF SCIENTIFIC PLANNING AND PROGRAMS

Our principal relationships with the National Science Foundation occur in two areas—in basic research in the physical sciences and in education and training programs. The largest NSF expenditures are generally in these two areas, whereas the education and training activities of the Commission are allocated less than 1 percent of our R. & D. budget. About 16 percent of our R. & D. expenditures are for basic research in the physical sciences.

PHYSICAL RESEARCH

In the physical sciences area the AEC has very close relationships with the National Science Foundation for the support of basic research in nuclear physics, metallurgy and materials, chemistry, solid state science, and certain phases of engineering research. Several methods are used to coordinate our interests in the support of basic research. First of these are two formal interagency Committees established under the auspices of the Federal Council for Science and Technology—the Technical Committee for High Energy Physics (TCHEP) and the Coordinating Committee for Materials Research and Development (CCMRD). These Committees include both NSF and AEC membership (the Chairman of the TCHEP is Dr. Robertson of NSF) and meet periodically to review scientific, budgetary, and administrative problems in the support of research in their respective areas of interest. These Committees serve a very useful and important purpose in the effective coordination of important areas of research. Secondly, the AEC and NSF both have representatives on the Solid State Sciences Panel of the National Research Council of the National Academy of Sciences (NAS–NRC) and both have liaison representatives to the Division of Physical Sciences and the Division of Chemistry and Chemical Technology of the NAS–NRC. These divisions of the NAS–NRC, working with the various agency representatives, serve as one of a number of means of communication with specific segments of the scientific community. The Solid State Sciences Panel, for example, is composed of senior scientists from all segments of the American scientific enterprise—industry, university, Government and not-for-profit laboratories, and the research-sponsoring agencies.

Twice yearly the Panel meets at a center of scientific activity to learn about the research conducted at that center and to hold a business meeting at which substantive issues affecting this area of science are discussed. The Panel forms a very effective bridge between Government and the solid state sciences community at large for exchange of points of view, identification of problems affecting the national health of the field, and for proposing the direction of future

scientific activity. Both NSF and AEC, as well as other agencies, are represented on this panel.

In addition to these formal Committees there are about eight informal interagency groups concerned with program coordination in such areas as nuclear structure physics, information systems, metallurgy, chemistry, and engineering research. At least three of these informal groups were established at the suggestion of the NSF. In the chemistry area for example, a group known as the Federal interagency chemistry representatives meets to exchange information on program status and problems involving more than one of the agencies. Meetings are attended by representatives from each agency having idenifiable basic chemistry programs in universities. This group was formed about 1952 by Dr. Kirner, retiring head of chemistry programs at the NSF. It has been effective and has helped avoid many of the possible pitfalls in Federal support of basic research in universities. At the most recent meeting, a committee report on AEC-supported chemistry research at universities was discussed as well as more general questions dealing with university research such as support of an investigation by a single agency versus several agencies; policies on payment of faculty summer salaries, support of foreign travel: and ratio of proposals received to those accepted.

The AEC and the NSF are the agencies principally involved in providing low-energy accelerators to universities. Proposals are jointly discussed and decisions reached regarding the strongest proposals and as to the agency which will provide support to a given proposal if funds become available. For example, several years ago both the AEC and NSF had proposals from a number of universities for new tandem Van de Graaff accelerators. It was jointly agreed that the three top proposals were from Rochester, Yale, and Minnesota. It was further arranged that the NSF would support the Rochester proposal and the AEC support the Yale and Minnesota proposals.

In the nuclear physics area we feel it is important that the NSF have the capability and the willingness to provide more support to the smaller schools—to provide the seeding and encouragement to those institutions which are not presently competitive in quality of research with the major universities. We emphasize the support of technical excellence in research. As part of this process we have been able to help the further development of such institutions as the University of Maryland, University of Colorado, and University of Oregon. In these cases the AEC has provided accelerators around which have developed, or are developing good nuclear physics research programs. We do, therefore, have several examples where we have recognized good potential, and by providing research support have brought these programs to the forefront of excellence. However, we still find that a large number of colleges and universities are unable to obtain Federal support for nuclear physics because they are too far from the top in the quality of their proposed research undertakings.

I favor the initial thrust of the National Science Foundation's science development program of placing high-ranking institutions even

closer to the top since it is a most efficient way of developing additional excellence rapidly. This is absolutely necessary if we are to keep up with the education of the rapidly increasing student population and at the same time carry on sufficient high-quality research. Thus, I can only conclude that additional funds are required for NSF in order that some seed money can also be provided to the lesser recognized institutions to build up their capabilities in specific areas such as nuclear physics. Perhaps one way to accomplish this is a considerable expansion of the science development program to permit the rapid development of a much larger number of institutions than is possible with the Foundation's current budget.

In the fields of physical research such as chemistry, metallurgy, and physics and also in certain areas of fundamental engineering research there are very frequent contacts between NSF and the AEC which are in addition to the formal and informal committees or groups which I mentioned earlier. Lists of proposals received and of actions on pending proposals are routinely exchanged each month. Telephone contacts between the AEC and NSF individual program administrators occur very frequently, sometimes almost daily, for final checks before actions are taken on proposals in those cases where an investigator has submitted proposals to both NSF and AEC. For proposals still under review by both agencies, discussions take place on scientific content of proposed programs, proposed equipment purchases, fraction of the investigator's time to be spent on the research, etc.

Quite often the technical reviews of a given proposal will be exchanged or discussed to insure the maintenance of quality standards, to obtain a broader evaluation, or to reduce the burden on the scientific community which reviews the proposals.

The matter of multiple-agency support to individual university scientists is a matter of increasing interest, especially in the chemistry and materials sciences areas. The solid state physics program staff of the NSF has recently taken the initiative to bring solid state physics administrators of all agencies together on an approximate monthly basis and has become the focal point for collection of work statements and budgets for all Government contracts and grants to universities in this area of science. The NSF staff has analyzed the data, and the agencies are working together to reduce multiagency support of individuals and thereby reduce chances of overfunding, overlap of support, and similar problems. Upon receipt of a new or renewal proposal, an agency administrator can telephone NSF and receive a fairly accurate statement of the proposer's other Federal involvements and commitments. Representatives of the Science Information Exchange (SIE) attend these meetings. The solid state physics administrators are now developing a coding so that the system can be questioned regarding the amount of money going into subcategories of this broad field of science. This enables studies to be made of the relative level of support of the several subcategories. It is anticipated that the system data will be fed into the SIE and it may serve as a model for other fields of science.

BASIC NUCLEAR ENGINEERING RESEARCH

About 3 or 4 years ago, the academic nuclear engineering community began expressing its dissatisfaction with the Federal support picture for basic nuclear engineering research. The prevalent feelings were that in the AEC such research proposals fell in a "gray" area between basic research and applied research, and were accepted by neither program area; and that a similar situation existed in the NSF with respect to its Physics Section and Engineering Section. These feelings were summarized and formally expressed in a report prepared and submitted to the AEC by a group of representatives of several professional societies and organizations.

Therefore, the AEC included in its fiscal year 1964 and fiscal year 1965 budgets requests for funds to provide for a separate category under the physical research program entitled "Basic Nuclear Engineering." In fiscal year 1964, this item was deleted by the House Appropriations Committee; in fiscal year 1965, it was deleted by the Joint Committee on Atomic Energy. The JCAE stated in its authorization report that it believed the necessary research could be conducted under the Commission's existing programs. Thus, nuclear engineering research proposals continue to be accepted for review within existing programs, as they have been in the past. The criteria used in evaluating these proposals are generally the same as those used in evaluating other proposals received by the program divisions concerned; that is, relevance to AEC interests, and scientific merit.

At the present time, the Commission's applied programs support about $3 million worth of research in universities' engineering and physics departments. Additionally, our basic research programs support a substantial volume of research in engineering departments as universities, but it must be admitted that this research is more science oriented than engineering oriented, which is a consequence of the nature of the proposals submitted by these departments.

It is true that in the past few years the university community has found it difficult to obtain support for new proposals, particularly in the areas of nuclear engineering and basic reactor physics. As much as anything, however, this has resulted from an insufficient amount of funds to satisfy all needs coupled with our assessment of relative priorities. We will, of course, continue to try and support outstanding research proposals in these fields. However, in view of this situation, and the overall benefits of such research, we suggest that it would be quite appropriate for the NSF, in its role as the balance-wheel for support of scientific activities, to request increased funds for university research in nuclear engineering. This would be entirely consistent with the statement in the Legislative Reference Service's report to this committee which states "the responsibility for any expanding Federal support of basic research may increasingly be thrust upon non-mission-oriented agencies." I will have more to say about a related aspect of this problem a little later.

To summarize our relationships in the support of basic research in the physical sciences, therefore, I should state that, of all of the agencies concerned with support of basic research in this area,

the one with which AEC has the most frequent contact is the NSF. Invariably we have found the NSF cooperative and anxious for close coordination.

EDUCATION AND TRAINING ACTIVITIES

I would now like to turn to the second major area of AEC–NSF relationships: education and training activities. NSF–AEC interactions in this area are also very close, especially since we have one program which is jointly funded by the two agencies. The specific educational programs which each agency undertakes are the following:

First, AEC has a program of nuclear teaching equipment grants to colleges and universities. Major emphasis in the AEC program is to provide equipment for the training of graduate students; our secondary interest is in the training of advanced undergraduates. To date we have provided equipment to about 650 institutions, from junior colleges to universities which are among the major graduate centers in the country. The NSF, on the other hand, provides equipment grants to similar institutions, but for all fields of science and solely for undergraduate teaching. AEC and NSF staffs periodically review lists from requesting institutions to identify duplications. In the few cases where duplications appear, only one agency makes the award. At the undergraduate level, AEC frequently refers the proposer to NSF for possible support and NSF may refer a proposal to the AEC if it is completely nuclear or graduate oriented.

This coordination works smoothly. To an increasing degree, NSF is providing nuclear equipment to those proposers where such equipment is only a minor part of a general-science program as contrasted to a nuclear-science program. This is beneficial to the individual institution, and permits us to concentrate our funds on those programs having greater relevance to our specialized mission. There are, however, not sufficient funds in AEC and NSF to meet all the educational needs in this area.

Secondly, AEC administers fellowship and traineeship programs in specific areas related to atomic energy program manpower needs: fellowships and traineeships in nuclear science and engineering, and health physics and industrial medicine fellowships. We also have AEC laboratory graduate fellowships and postdoctoral fellowships which provide for research experience in AEC facilities. The postdoctoral fellowships are primarily for individuals interested in teaching nuclear science and engineering. Our policy restricts fellowships to individuals whose stated intent is to prepare for atomic energy-related careers. It might be of special interest to this committee to mention that we recently instituted a traineeship program in order to further develop institutions which have qualified graduate programs in nuclear engineering but relatively low graduate enrollments in this field. We provide funds which permit the institution to bring in fellowship students. This tends to avoid the concentration in a few universities which occurs when the fellows select the institution they wish to attend.

Several times a year a meeting of all Federal fellowship administrators, together with a few invited administrators from national fellowships programs sponsored by private funds, is convened under the nominal chairmanship of the NSF fellowship administrator. Information is exchanged relative to past year's performance and plans for the following year. Appropriate levels of stipends, dependency allowances, and educational allowances in lieu of tuition and fees are discussed. The meeting serves as a general clearinghouse for information exchange and problem discussion. It is not formalized, binding decisions are not reached. Relative to AEC–NSF specifically, a continual informal exchange of statistical data, plans, and existing or anticipated problems is maintained. Our administrative procedures for fellowships and traineeships are kept as identical to NSF–NIH–NDEA procedures as is feasible.

The third program, and the one in which the two agencies have joint participation, is the faculty institute program. The AEC administers two parallel programs—first, short topical conferences for undergraduate and graduate faculty of engineering institutions, fully funded by AEC working through the American Society for Engineering Education and, secondly, AEC–NSF faculty institutes and conferences for college and high school faculty in specialized topics such as radiation biology or isotope technology. Proposals for the AEC–NSF institutes are submitted to both agencies. The NSF panel review system is used for selection of the host institution. At present, AEC's role in this selection process is minimal but we hope to increase our participation in the near future. AEC contracts for the operation of the courses by the host institutions, whereas NSF provides stipends and dependency allowances for the participants. This jointly sponsored program constitutes about 10 percent of the approximately 400 or more institutes supported each year by NSF alone.

The jointly funded institutes are beneficial to both agencies and therefore to the educational community. They provide for programs that might not be possible through single agency funding. This widens the impact of atomic energy upon science curriculums at all levels, enhancing the NSF mission and contributing directly to the AEC mission.

Finally, the support of nuclear reactors at universities is of interest and concern to both agencies. Nuclear reactors on the university campus may be utilized both for teaching and research. In August 1956 the AEC established its educational assistance program which, at that time, included provision for grants to schools to obtain low-power nuclear reactors for use in education and training. The AEC contribution toward each such reactor was subsequently limited to $150,000. Grants totaling $3.6 million were made for 32 of these teaching reactors. In addition, our educational assistance program provides for the loan of fuel for these reactors, as well as for university research reactors, at no charge for use or reprocessing. We also provide other associated reactor materials without charge.

However, we no longer make grants for the construction or purchase of teaching reactors. In 1956, there was informal agreement between the AEC and NSF that NSF would assume responsibility

for the support of university research reactor construction and that AEC would retain concern for the specialized training reactors. This agreement recognized the primary interest of the NSF in basic scientific research in all areas of science, particularly on the university scene, and the broad, interdisciplinary nature of many research programs built around a reactor.

In the period, 1956–60, NSF awarded 14 research reactor facility grants to 11 universities, at a total cost of $4.5 million. Beginning again in August 1961 to the present, there have been six grants to five universities, totalling $1.5 million. Only two of these grants—Berkeley, Oregon State—were for the establishment of totally new reactor projects. In addition to these mechanisms for the support of research reactors, both agencies fund certain research activities in which the university reactors are either the major subject of the research, or contribute to the research as an experimental tool.

We have found, however, as in the case of basic nuclear engineering research mentioned earlier, that neither agency has been able to support the use of these university research reactors at the levels desired and recommended by the academic community and by a panel of experts convened by the National Academy of Sciences-National Research Council under NSF sponsorship. This panel, which issued its report in October 1964, recommended that "the interested agencies consider the possibility of funding jointly the major portion of the operating costs of those university reactors making (or showing promise of making) a significant educational and research contribution to science and technology." The panel indicated that there have been 362 master's and 185 doctor's degrees granted to students using the 25 reactors surveyed, through December 1963.

The NSF and the AEC are continuing to examine this problem of support but both agencies are finding it increasingly difficult to provide the funds requested in the face of increasing demand for support in other areas coupled with the receipt of highly meritorious requests for support in these areas. Our relationships with NSF in this area have been excellent; there is complete interchange of information and ideas.

OTHER AREAS OF NSF–AEC INTERACTION AND COOPERATION

I have just described in some detail the two main areas of interaction between our two agencies. Let me now briefly mention some other areas of interaction. With respect to our relationships in biomedical research, it has been accepted and enthusiastically endorsed that support of the broad field of systematic biology is a prime responsibility of the NSF. Molecular biology, genetics, developmental biology, and metabolic studies are areas of common interest and thus lead to considerable contact and interchange. Some of our scientific staff members (from our Division of Biology and Medicine) are observers on NSF panels in the fields just mentioned. This participation involves review of NSF research proposals and also serves as an excellent interchange of program information and contemplated actions on proposals between the two agencies. Contacts and infor-

mation interchanges in these areas of common interest are very satisfactory and are similar to those which occur in the physical sciences, which I have already mentioned. In the life sciences area, however, our prime contacts are with the NIH rather than with NSF. On a multiagency basis, AEC professional staff serve on a large number of interagency committees or subcommittees—at least a dozen such groups—on which there is also representation by NSF. Such groups are generally very effective in providing for the exchange of scientific information, for assisting in the Government-wide planning of research efforts and selecting areas for emphasis, and for coming to general understandings about individual agency programs.

We, of course, have other, much more limited interactions with NSF in providing data on R. & D. funding levels, getting NSF assistance on manpower surveys, in the technical information area and in other staff-type relationships.

THE FUTURE ROLE OF THE NATIONAL SCIENCE FOUNDATION

Before closing, I would like to discuss briefly the overall activities of the Foundation and to suggest some areas for further emphasis. As Dr. Haworth stated in his introduction to the Foundation's annual report for 1964, "* * * continuing progress in science and technology is essential to the public welfare * * *." In this age of the scientific revolution I believe it necessary that strong and increased support be given to the activities of the NSF. Dr. Waterman and Dr. Haworth, my former colleague on the Atomic Energy Commission, both deserve the highest praise for their inspired leadership of the Foundation. As a single organization the Foundation cannot be expected to take the leadership in all aspects of the support of science in this country.

It should be abundantly clear that the various mission-oriented agencies each need to continue their support of applied research and development, basic research, and related education and training. The diversity of support for such activities, while it has been questioned by some, is one of the main reasons for this Nation's current scientific leadership. But the needs are great, and it is becoming increasingly more difficult for the mission-oriented agencies to provide the required support for basic research. In the AEC, because of competing mission demands, our budget for basic research is not structured to take advantage of many worthwhile opportunities, and neither can it provide for increased education and training opportunities which must be provided in order to maintain this Nation's scientific and technological leadership.

It thus must fall, in large part, upon the National Science Foundation to support those areas of research not now receiving adequate attention, and to provide for additional educational opportunities for high school undergraduate and graduate students and faculty in the sciences. Improvement in the quantity and quality of scientific research in the Nation's colleges and universities is an important ingredient for the improvement of the educational activities of these institutions.

Research and teaching are closely related. Historically, scholars have found that teaching, without research, can become static and sterile. I recall the dynamic role of the research in my own teach-

ing experience. I found that, during the years I taught nuclear chemistry, I did not use the same lecture notes twice.

I was engaged in research, and the field was advancing rapidly. It was possible for me to transmit to my students new knowledge and new laboratory techniques as they unfolded. Distinguished research by the teaching faculty has been an essential source of the greatness of universities, and it should endure as a measure of academic excellence in the foreseeable future. In the recent hearings, chaired by Congressman Reuss, before the Research and Technical Programs Subcommittee of the House Committee on Government Operations, it was the overwhelming consensus of all the witnesses, both from the academic community and the Government, that Federal research support on the university campus has done much to improve both graduate and undergraduate teaching.

Thus, the Foundation should be provided with additional funds: First, to support the highest quality research; second, to support research projects at some of the institutions now less well known for research; and third, to expand its program of science development grants and its so-called institutional base grants program, which would give the educational institutions the flexibility to use funds according to their individual needs. Serious considerations among the other science-supporting agencies are also underway to assist in the goals of these last-mentioned efforts.

I would also urge additional efforts in curriculum development. I had the great pleasure of personally participating in one of the efforts to improve the chemistry curriculum in the secondary schools, the so-called chem-study. These efforts have been very successful, and should continue to be supported. After all, a teacher's inspiration at an early age has been found to be one of the most important factors in turning young people to science. However, the young people who have benefited from these course improvements are now entering our colleges and universities and thus I believe that there should be increased emphasis to improve and develop the higher education curriculums. This is a logical outgrowth of the initial efforts.

I have only mentioned a few of the Foundation's programs. I do not mean to imply, by lack of reference to other NSF programs, that I consider them unimportant.

I can assure you that the AEC will continue to do its part in strengthening science and science education in this country.

In closing, let me restate that our relationships with the National Science Foundation have been most amicable and cordial. A number of cooperative arrangements exist and work well. Many formal and informal means of cooperation and interchange exist and are frequently used, some almost on a daily basis. We are very pleased with the effectiveness of these relationships.

Mr. DADDARIO. Thank you, Dr. Seaborg. Mr. Chairman.

Mr. MILLER. I want to congratulate Dr. Seaborg on this statement. I have found it very interesting and refreshing. I want to thank him also for taking time out of a very busy schedule to give us the benefit of his long experience.

Mr. DADDARIO. Thank you, Mr. Chairman. Dr. Seaborg, you stress the importance of a teacher's inspiration to the students at an early age. I wonder if you might tell us your idea how these fellowships,

which the Government gives, ought to be handled in regard to their teaching loads. I have gotten some indication from the academic community that the fellowship recipients shy away from teaching to an inordinate degree, and that the people who teach are the less capable people and, therefore, there is less inspiration.

Dr. SEABORG. I think the fellowships should be awarded in such a way that they can contribute to the teaching function. I believe that the fellowships for graduate students should in all cases allow for teaching experience by the graduate student during his graduate career. I also think that the fellowships awarded to teachers for the purposes of bringing them up to date in their fields should pay attention to the teaching experience and teaching role of the recipient as well as the research role.

Mr. DADDARIO. How does the AEC handle its fellowships in this regard?

Dr. SEABORG. The AEC permits and, further than that, emphatically encourages, teaching by the recipients of its fellowships.

Mr. DADDARIO. It was my understanding from a discussion with Dr. Haworth that the National Science Foundation, in order to stimulate its fellowship participants to additional teaching, allowed the universities to grant up to a thousand dollars for teaching obligation. When they did this, the number of people who taught in the fellowship areas jumped up from about 10 percent to 25 percent. Do you have such a requirement, and, if so, what is it?

Dr. SEABORG. Yes, we allow the institution to pay the fellow or trainee for teaching up to a maximum of $1,000 per year. We also have in our traineeships and fellowships a part of the monetary stipend that goes to the university—do you remember how much it is?

Mr. COURTNEY. We are allowing an educational allowance of $2.500 per student, in lieu of tuition and fees.

Dr. SEABORG. $2,500 per student goes as an educational allowance. That was Mr. George Courtney of our Division of Education and Training.

Mr. DADDARIO. $2,500 directly to the student as an educational allowance?

Dr. SEABORG. No; to the university to be used by the university to strengthen its programs, which can include the teaching function.

Mr. DADDARIO. Dr. Seaborg, might a greater obligation be placed on the high-level student himself who is at such a level that he deserves to be a recipient of a fellowship rather than give it to the university who might then not be able to convince him to teach? In your statement, you talked about being engaged in research to the extent where you never used the same lecture notes twice. I would expect that this would be the most stimulating kind of activity around which the student could be engaged. I think that inspiration of students is an important function of our research activity and that we should use our best people in the process of their research to be inspirations.

Dr. SEABORG. Yes. I think that research and teaching go together very well, and research and teaching in graduate education should be tied together at every possible opportunity.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Dr. Seaborg, there is a question that has bothered me for a long time that does not specifically pertain to the relations between NSF and AEC but nevertheless does pertain to both of you.

Some time ago I read an account of a gentleman who in the early days of wireless telegraphy, or radio transmission, succeeded in getting hold of quite a bit of money by giving lots of lectures and giving himself credit for a lot of things that he really was not entitled. He was almost an imposter, and more than once he committed virtually what amounted to larceny to the ideas of European scientists. Right now I have forgotten what his name is.

Dr. SEABORG. It's probably just as well that you fail to recall his name.

Mr. DAVIS. I agree with you. You never hear the breath of suspicion on the part of anybody that all of our Government money for basic research and development isn't being well spent and isn't being put in the most capable hands. I would like to have your comment as to whether or not there is a possibility that we are misspending some of our Government money. Are you satisfied that all of our money so far as you know is being well spent?

Dr. SEABORG. I think the overwhelming proportion of it is being well spent, but I am sure that some mistakes are made. I think that this is caught in the review procedure when the grants or contracts come up for renewal, at least the large proportion of such cases are discovered in the review procedure.

Mr. DAVIS. Do you refer there to duplication or just an error?

Dr. SEABORG. I was referring specifically to your question of whether some of it might be misspent, and I had in mind less than adequate quality of research results. As to duplication, I don't consider that to be a very serious problem. That is taken care of by the nature of science, in the publication procedure, and so forth. Good scientists cannot afford to duplicate unnecessarily the work of other good scientists. Some checking of results, of course, is necessary, and I would not regard that as duplication in the sense that the term would be used here.

Mr. DADDARIO. You have spelled out the joint efforts you have with NSF, NIH, and others which I imagine are directed toward this objective as well?

Dr. SEABORG. Yes, toward both objectives: toward eliminating the low-grade work, the less-than-adequate research work, and eliminating the undesirable duplication.

Mr. DAVIS. There is one other question I had, and that refers to the Science Information Exchange which you refer to on page 9 of your statement. Just how large a group does that exchange serve? How many agencies feed information into it or receive information from it?

Dr. SEABORG. The Science Information Exchange that I refer to is operated by the Smithsonian Institution, and this collects information on the research in progress under Federal support by all departments.

Mr. DAVIS. Does it try to handle the entire spectrum of scientific work?

Dr. SEABORG. It handles the physical and life sciences.

Mr. DAVIS. Isn't there a private company, Documentation, Inc., which does the same sort of thing?

Dr. SEABORG. Yes. I think that company does it for NASA.

Mr. DAVIS. I was not aware that it was restricted to NASA, but I know it does serve NASA.

Dr. SEABORG. I don't know either, whether it is restricted to NASA or not.

Dr. VANDERRYN. They are a contractor to NASA I believe. We contribute our basic research information to the Science Information Exchange.

Mr. DAVIS. Has your experience with Science Information Exchange been good? For example, suppose you were going to assign a given task to some university, and you first wanted to screen it through Science Information Exchange to see if it had already been done or if it were in progress at some other university, do you use SIE for that purpose?

Dr. SEABORG. Yes, we do. We also have liaison through a member of our staff on the board.

Mr. DAVIS. Has it been successful?

Dr. SEABORG. We think it has been quite successful.

Mr. DAVIS. I have heard it said in testimony before this committee that it is quite often true that when you go to code a description of some particular task, that quite often the title will be about as long as the description. If you want to pinpoint what some particular worker is doing, it is a very difficult thing to do. If this is true, I thought that perhaps your experience might have been less than satisfactory.

Dr. SEABORG. No. It is difficult to describe briefly in the title—the content of a scientific research program in such a way that it can be readily retrieved through a computer system or equipment of that type, but I think that SIE is doing a good job. There is, of course, a continuous attempt there to improve the information retrieval system.

Mr. DAVIS. It is true, too, is it not, that the men engaged in that particular field of inquiry stay in close touch with each other?

Dr. SEABORG. Oh, yes, they do that by exchange of their own papers, preprints and reprints of their published work, and by correspondence, and at scientific meetings, in symposia, and in cases of a particularly exciting result, by telephone.

Mr. DAVIS. I notice that AEC and NSF both put on many institutes and symposia, which I believe to be a good thing.

Dr. SEABORG. Yes. I think this is one of the best means of exchanging information—scientific information.

Mr. DAVIS. Then you do not have to rely entirely on SIE to prevent against duplication?

Dr. SEABORG. No.

Mr. DAVIS. You have many human contacts.

Dr. SEABORG. Oh, yes. And there are lots of other areas of scientific results, nongovernmental and broadly in the universities, internationally in other countries, and so forth that are handled by abstracting services of which there are quite a number. The chemical abstracts of course, of the American Chemical Society is one of the chief such services; the physics abstracts partially supported by the Ameri-

can Institute of Physics; the Nuclear Science Abstracts which the Atomic Energy Commission itself prepares and publishes, and many other abstracting services play a very important role in this connection.

Mr. DAVIS. Thank you. That is all.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Dr. Seaborg, I would like to thank you for your emphasis on coordination. I think most of us realize this must be a serious problem in the data collection field. As I understand it, coordination is achieved both through these formal panels and through the informal interagency groups that you mentioned. Do you sometimes have what we might call jurisdictional disputes that you cannot solve, and do you ever appeal to the President's Scientific Adviser for decisions? In other words, how do you resolve matters of interest to both agencies which may result in duplication?

Dr. SEABORG. Well, I think that in the case of our relationships with NSF we have been able to resolve any differences ourselves. I can't remember any unresolved differences.

Mr. CONABLE. You cannot remember having had to appeal to a higher authority? One of the functions of the President's science adviser is to coordinate agency program. This function, you will remember, was taken away from the National Science Foundation.

Dr. SEABORG. I think in such an instance we would use the science adviser, the Office of Science and Technology, or the Federal Council for Science and Technology, if it were a matter of some inportance.

Mr. CONABLE. Has it been possible to reduce any duplication simply through these informal procedures and through constant contact?

Dr. SEABORG. Yes. I do not recall any instances where there has been dispute with the NSF.

Mr. CONABLE. Which is the more important contact, the informal interagency groups or the panels?

Dr. SEABORG. I would imagine the informal day-to-day telephonic contact probably does more work than anything else.

Mr. CONABLE. There have not been any unresolved problems that you know of under this procedure?

Dr. SEABORG. No, sir. None of any consequence have come to my attention, and I am certain they would have if there had been any problems of any consequence.

Mr. CONABLE. Thank you. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Dr. Seaborg, there was not too much said in your prepared remarks with regard to support of either international science research or information dissemination. The AEC does have programs in these areas, does it not, as well as the NSF?

Dr. SEABORG. Yes. You mean the support of scientific research?

Mr. BROWN. I mentioned both things, the support of scientific research in other countries and the exchange of information through translation and other types of services.

Dr. SEABORG. Yes, we do. We have some support of research in other countries, I guess more particularly in the area of biology and medicine and nuclear power reactor development. That is, in the area of the peaceful uses of atomic energy. We have exchange of information through agreements—special agreements and bilateral agreements—with a large number of countries, 30 or 40 countries, in

the field of the peaceful uses of atomic energy. Then, as I indicated, we have a rather substantial science information program of our own of which the Nuclear Science Abstracts is a good example. These are abstracts of work in nuclear science from all over the world, from all countries where such work is being conducted. We have a program for the preparation of monographs and a program of support for attendance of scientists at international meetings, just to mention a few of the areas in which we cooperate.

Mr. BROWN. Is there an underlying policy which governs our actions as far as support of nuclear scientific research in other areas that could be expressed relatively simply?

Dr. SEABORG. Well, it is basically that we support such work when it can be done better there than anywhere else.

Mr. BROWN. You made one brief reference on page 2 to a description of how breakthroughs occur and how the AEC would begin to support them when it became obvious that they are of concern to the nuclear program. You mentioned superconductivity and its use in controlled thermonuclear research. While this question is not particularly relevant to relationships between AEC and NSF, I have noticed in one of the AEC's own publications that our expenditures in the field of controlled thermonuclear research have been gradually increasing over the past 4 or 5 years but that the Russian expenditures have been increasing at an even faster rate. To what degree are we conversant with the work that Russians are doing? Why do they find more opportunities in this field to spend money than we do? Why are their expenditures 50 percent more than ours?

Dr. SEABORG. We are quite conversant with their work in this field. Under the exchange agreement, the Agreement for Cooperation in the Peaceful Uses of Atomic Energy, which was signed by Chairman Petrosyants of the State Committee of the U.S.S.R. on the Utilization of Atomic Energy and myself in May of 1963, we have had a number of exchanges and particularly exchanges of teams—an American team went to the Soviet Union and a Soviet team visited us in the United States to look at the work in controlled fusion reactions.

Mr. BROWN. That is what I was referring to specifically.

Dr. SEABORG. Specifically, we have had exchanges of teams between the United States and the Soviet Union in the field of controlled fusion reactions. With respect to whether we could think of a broader program than we now have, I would say that our scientists certainly could do that. I think they feel that they are a little bit under wraps due to the perennial problem of budget limitations. Our program effort has remained essentially level in the past 4 or 5 years. We are having a review of our program by a high level panel, which we would hope would be able to report recommendations as to the future of our program before the end of the year. This panel is under the chairmanship of Prof. S. K. Allison of the University of Chicago. So, I would say we are in a sense at a sort of crossroads in our controlled-fusion program and may recommend different directions and possibly an expansion of the program when we receive the report of that special review panel.

Mr. BROWN. It just seems to me if we had known 10 years ago the extent to which the Russians were doing work in the satellite field it might have modified our policies a little bit at that time, and here

we seem to be aware of the fact that they are devoting an unusual amount of effort to a field that could have rather important implications.

Dr. SEABORG. Yes, although there are some differences. It is a long-range program; it is a program in which the results of the investigations are published and we think will be generally available.

This is a very important area of investigation. The goal of being able to literally burn the heavy hydrogen in the water of the oceans to produce energy is a very important one. But the problems of containing the material and of reaching the very high temperatures that are required are so great that it is likely that we won't be able to solve the problem to the extent of obtaining practical large amounts of energy from the fusion reaction before the end of this century. So, the problem doesn't have the immediate urgency of the space program, but the failure of this Nation to keep sufficiently knowledgeable in the field of high-temperature plasmas would be undersirable.

Mr. BROWN. If we spent twice as much money, could we do it twice as fast between now and the end of the century?

Dr. SEABORG. No; I do not think we could. But I think we could usefully spend more money than we are, in shortening the time. It would be difficult to predict how much it would shorten the time.

Mr. BROWN. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I would like to ask a question or two of Dr. Seaborg.

Do the breeder reactors, such as the Enrico Fermi reactor, promise an early solution to the provision of much increased power, or not? How significant is this role compared to that, for example, of hydrogen fusion?

Dr. SEABORG. Oh, the breeder reactor will play an important role in producing power in our country and throughout the world, I think, before hydrogen fusion will do so. Specifically, the breeder reactor will play not only an important but an essential role in producing electrical energy in the future. We have a program in the United States under the auspices of the Atomic Energy Commission whereby we are giving increasing attention to the advanced reactors that use nuclear fuel, fertile material such as uranium and thorium, more efficiently.

We are developing first what we call advanced converter reactors which produce nearly as much fuel as they consume while they are producing electricity. Somewhat concurrently, but a little later so far as the final goal is concerned, we are developing breeder reactors which produce more fissionable material than they consume in the process of developing electricity. These types of reactors are absolutely essential because if we continue to use up our uranium and thorium with the present water-cooled reactors, which seem to be on the verge of being economically competitive but which do not use the nuclear fuel very efficiently, we would find that nuclear fission was not contributing to our long-range energy needs as much as nuclear fission should or as much as nuclear fission can and must do in the future. So, the development of the breeder reactor, as an important part of our program, is coming along quite well, and the time scale is approximately such that in the 1980's we should have rather large breeder reactors which are producing electricity and additional fuel in the process of producing electricity to be used for fueling other reactors.

Mr. VIVIAN. Have any requests for funding for such research and development been denied by the Congress?

Dr. SEABORG. I would not say that there has been no request for funding denied by the Congress, but I do think that the funding for the development of breeder reactors that has been provided by Congress is at a pretty reasonable rate.

Mr. VIVIAN. Have there been any significant deletions at the Bureau of the Budget level?

Dr. SEABORG. I think that there have been deletions in detail at the Bureau of the Budget level, but again I think that the overall level of support has been quite good. We are at the present time, as I indicated, giving our greatest attention in terms of funding to these advanced converter reactors, and we have two of these in the fiscal 1966 budget and another one that we look forward to funding in an early subsequent year.

Mr. VIVIAN. I would like to switch to another subject. In terms of the history of funding for research and development within the Atomic Energy Commission, how has research and development funding fared over the past 10 years as compared to the production or utilization of nuclear materials or explosives? How has the R. & D. sector fared?

Dr. SEABORG. Quite well. The research and development, and in fact the whole area of the peaceful uses of atomic energy has been steadily increasing. Due to the fact that the need for fissionable materials for nuclear weapons seems to be more than adequately met, the budget for the production of fissionable materials and the production of nuclear weapons from fissionable materials has been reduced, more especially in recent years.

An example might be our budget for the current fiscal year, for fiscal 1966. There was an increase in the budget for all aspects of the peaceful uses of atomic energy and a decrease in the budget for the purchase of raw material, uranium, for the production of fissionable materials and for the fabrication of weapons from fissionable materials. I think I could put this in some perspective by indicating the extent of this decrease. Three years ago about 70 to 75 percent of the budget of the Atomic Energy Commission was concerned with these aspects of the production of nuclear weapons. In fiscal 1966 the budget of the Atomic Energy Commission is divided about equally between the peaceful uses of nuclear energy and all aspects of the production of nuclear weapons.

Mr. VIVIAN. I would like to switch to a question of manpower. I have had a fair number of persons who have been in my own personal employ in times past who were trained in nuclear physics, typically in either theoretical or experimental nuclear physics, and who drifted out of that field almost as soon as they obtained a Ph. D. I had the impression that that is quite a widespread phenomenon. I am not quite sure that is undesirable at all in that I think this training is an excellent background. I would rather see more of this than less. Is this a typical situation in your view? Are there a larger number of people trained in advanced and theoretical nuclear physics than are used by the nuclear industry, I don't mean industry itself, but the entire collection of users, governmental and nongovernmental?

Dr. SEABORG. There are a large number of the graduates in nuclear physics that are used by industry and by the universities, but, as you

say, there are an appreciable number that go into other fields. I believe there are some who are even trained in other fields that go into the nuclear industry. I think this is a good thing, and I don't believe that there is anything about the situation at all that alarms me.

Mr. VIVIAN. I notice you have evaluation by peers mentioned in your remarks, and you refer to the fact that most programs are evaluated by three or more persons in the field. Would you say this affects 50 percent, or greater, of the amount of money awarded under the various grants and contracts?

Dr. SEABORG. Oh, yes. I think that in the area of support for basic research in the universities this procedure is used essentially 100 percent of the time.

Mr. VIVIAN. And the exceptions, then, would lie in the contracts to industry or——

Dr. SEABORG. The reason I put it that way is we have a substantial part of our support for research covering the work in our own large multipurpose national laboratories.

Mr. VIVIAN. A final question, do you have any comments on the subject of geographical distribution of the funds utilized for atomic energy? Is it concentrated in any particular areas historically or at the present time?

Dr. SEABORG. I think that in the area of our support for research in universities through our contracts it is quite widespread. We have something of the other of 500 contracts in the Division of Research and about the same in the Division of Biology and Medicine. We have made analyses of the spread of these throughout the country which indicate that there is quite a broad spread there, and perhaps they would be worth submitting for the record if you would like to have them.

(The information referred to is as follows:)

Mr. VIVIAN. I would appreciate receiving it. Does that also pertain to your major governmental centers?

Dr. SEABORG. Our major governmental centers, or so-called multipurpose laboratories, or national laboratories, sprang up in large

part during the war under conditions where such criteria as isolation often were important. The net result has been that we have a rather good spread in the geographic location of these laboratories, as you probably know. We have one of the major ones in the South at Oak Ridge, Tenn., and another laboratory connected with one of our production centers in South Carolina, the Savannah River Laboratory; we have the Pacific Northwest Laboratory in the southeastern part of the State of Washington; and, of course, we have the Los Alamos Scientific Laboratory in New Mexico; and, in addition, laboratories on the east and west coasts, the Brookhaven National Laboratory on Long Island, N.Y., and the Lawrence Radiation Laboratory in Berkeley and Livermore, Calif.; and the Argonne National Laboratory in Chicago. There are other laboratories as well, but all and all I think the geographic spread is, although it may be said to have resulted somewhat accidentally, quite good.

Mr. BROWN. You don't have any in Texas, do you?

Dr. SEABORG. We don't have any of these national multipurpose type laboratories in Texas; no, sir.

Mr. DADDARIO. Dr. Seaborg, I have a whole series of questions which I hope to send to you for answers.[1] However, I would like to ask you one question now.

You have indicated that when mission-oriented agencies have difficulty in doing the required share of basic research, that the National Science Foundation should fill in the gap and play an increasing role. Have you given any thought to the type of growth that this would indicate, for example, percentage figures related to budget increases?

Dr. SEABORG. I think it would require something of the order of a 15-percent increase per year just to continue about the same degree of support as at present. There is about a 10-percent increase in the numbers of researchers in the universities and colleges annually and about a 5-percent increase in the cost of doing research, so that just in order to maintain the same degree of support requires an increase of about 15 percent per year.

Mr. DADDARIO. As you review the record, if you would like to enlarge upon that answer, please feel free to do so.

I want to thank you for your testimony, Dr. Seaborg, it has been most excellent. This committee will now adjourn to the same place tomorrow morning at 10 o'clock.

(Whereupon, at 12:22 p.m., the meeting was adjourned to reconvene at 10 a.m., Wednesday, July 7, 1965.)

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JULY 7, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

Our first witness this morning is an old friend of this committee, the Deputy Administrator of the National Aeronautics and Space Administration, Dr. Hugh Dryden.

Dr. Dryden, we are pleased to have you with us, as always, and we look forward to your testimony.

STATEMENT OF DR. HUGH L. DRYDEN, DEPUTY ADMINISTRATOR, NATIONAL AERONAUTICS AND SPACE ADMINISTRATION; ACCOMPANIED BY DR. HOMER E. NEWELL, ASSOCIATE ADMINISTRATOR, NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

Dr. DRYDEN. Thank you, Mr. Chairman and members of the subcommittee.

It is indeed a pleasure to appear before you this morning in connection with the comprehensive review that your subcommittee is making of the National Science Foundation. The National Aeronautics and Space Administration, as did its predecessor agency, the National Advisory Committee for Aeronautics, has had a long and satisfactory experience in its relationships with the National Science Foundation.

As a matter of fact, it was Dr. Vannevar Bush, in his report "Science, the Endless Frontier," who set forth the need for and suggestions that ultimately led to the creation of the National Science Foundation. He not only saw this need from his work with the Office of Scientific Research and Development during World War II and from his long years of association with the National Advisory Committee for Aeronautics from 1938 to 1948, but conceived the manner in which the Federal Government might meet it.

In the 15 years since the signing of the National Science Foundation Act by the President on May 10, 1950, the National Science Foundation has made an increasingly important contribution in promoting the progress of science in this country.

In carrying out its fundamental purpose of strengthening the basic research and education in the sciences in the United States, the National Science Foundation is engaged in a wide variety of scientific activity. It is concerned with the development and dissemination of information relating to scientific resources, including manpower, aimed at facilitating national decisions relating to strengthening the scientific effort of the Nation. It is engaged in the award of grants and contracts primarily to universities and other nonprofit institutions in support of basic scientific research, for research equipment, for the construction of laboratories of specialized facilities, and for generally strengthening an institution's scientific endeavors.

The latter is typified by the recently initiated Scientific Development Program. It supports national centers, such as the Kitt Peak National Observatory, where large facilities are made available for the use of qualified scientists. It awards graduate fellowships in science. It supports a wide variety of programs aimed at improving scientific education in the United States. Finally, it is intimately involved in the problems of scientific information acquisition, collation, and dissemination.

The National Aeronautics and Space Administration's program, which is seeking to expand human knowledge of the phenomena in the atmosphere and space, is the most comprehensive and complex scientific and engineering effort ever undertaken by man. In it is included extraordinary contributions in basic research. To the casual observer, the question which immediately arises is, Why should more than one group be engaged in carrying out basic research? The answer is a complex one; but to put it in the simplest terms, basic research is essential in any scientific and engineering endeavor. Thus any national program, such as the space program, the atomic energy program, our defense program, must carry out basic research in support of its mission. It may even be said in like sense that the National Science Foundation also has a mission. But its mission is a broad one covering all science as opposed to the more limited interest of the so-called mission-oriented agencies.

In carrying out its activities, NASA draws heavily on the results achieved in the promotion of progress in science by the National Science Foundation. To have a strong NASA, a strong AEC, or any strong new national scientific program that may arise in the future requires that this Nation maintain a strong National Science Foundation.

This strength, however, must be planned in the light of the scientific activities of the various Federal agencies as well as the scientific activities of the private sector of our country. The NSF must strive to develop a program that strengthens all of the science with particular attention being given to those areas that lie between the strong thrusts that are made by the mission-oriented agencies in the areas of direct concern to them.

The concept of plurality of Federal research support is one that has been accepted and endorsed by all branches of the Federal Government and by the academic community. In the case of my agency, the National Aeronautics and Space Administration, to be strong and viable requires a direct and intimate relationship with all segments of the scientific and industrial community that form the Gov-

ernment, university, and industrial team essential to the conduct of the space program. The problem of concern is not, nor should it be, one of a single agency supporting all research, but rather how the total activity is coordinated to assure that a wise total program is being pursued.

In this regard I would like to spend a little time discussing several activities of NASA that are intimately related with activities of the National Science Foundation to show how our activities are coordinated and how we work together for the national interest.

The first I would like to discuss is that of support of basic research. I have chosen to discuss the area of astronomy because is in reality the Nation's first space program. Further, the report prepared and issued in the latter part of the 1964, "Ground-Based Astronomy—A 10-Year Program"—the Whitford report—by a panel on astronomical facilities of the National Academy of Science's Committee on Science and Public Policy, provides the basis for comparing the role of the Foundation and the role of NASA in this field.

Astronomy is an area which illustrates the way in which NASA and NSF have shared the responsibility for maintaining this Nation in the forefront of astronomical research. I would like to review the kinds of support which each agency provides, how we coordinate our support, and why I feel a strong Foundation will strengthen the NASA program.

Prior to the establishment of NASA in 1958 the National Science Foundation was the single agency responsible for the overall support of astronomy. The establishment of NASA with a charter to expand human knowledge of space phenomena raised a question as to the role of the astronomer in space research. It was clear that the ability to observe astronomical objects outside the obscuring effects of the atmosphere would advance the science of astronomy by an amount comparable to the invention of the telescope itself. It was equally clear that orbiting a telescope and pointing it with the required accuracy would be one of the most complex and difficult tasks of the space program.

If, at that time, we had had to evolve a program of space astronomy while simultaneously training new astronomers it would have been many years before we could have even begun the development of our orbiting astronomical observatories. Fortunately, we did not have to wait, because there existed competent astronomers who had long recognized the potential of space astronomy, who had well-thought-out programs, and who were ready to exploit the opportunities provided by space flight. These astronomers existed because this country possessed the wisdom and foresight to provide, with public and (particularly in the case of astronomy) private funds the facilities to enable people with ability and interest in astronomy to train themselves to conduct research in astronomy.

It is imperative, particularly as the cost of research increases and the ability of institutions to obtain sufficient private support decreases, that the National Government adequately provide for the support of basic research in all the broad scientific disciplines, such as astronomy. How do we coordinate the NASA program in astronomy with the National Science Foundation support of the broad basic research in all of astronomy? As a result of the Whitford

report, recommending increased support of ground-based astronomy, we in NASA recently made a detailed reexamination of our policy in the support of astronomy. The National Science Foundation was requested by the Office of Science and Technology to assemble an ad hoc group of agency representatives to make a Government-wide assessment of the Whitford report.

I would like to quote two passages from the documents which NASA transmitted to the National Science Foundation as a part of our assessment of the Whitford report. These passages summarize our policy on the support of astronomy and the important role which we feel NSF must play:

> General support of astronomy in the province of the National Science Foundation: NASA cooperates with this and other Government agencies in an attempt to insure support of deserving programs and to discourage any possible attempt to stimulate competition between agencies. However, it is obvious that the exploration of space must intimately involve both astronomers and astronomical research. It is difficult to conceive of any area of astronomical research which has no contact with space exploration. Moreover, in many areas of its program, NASA urgently needs additional astronomical research both to plan its programs intelligently and to interpret the results obtained. Therefore, NASA has undertaken the support of both astronomical research and astronomical facilities in those areas of astronomy which most directly affect the space program. In addition, it has used the flexibility of its supporting research and technology program, its field center research, its training grants, and its facilities grants to support, at a lower level, an important broader base of astronomical research from which more closely mission-oriented research must arise.
>
> We recognize the close connection between ground-based astronomy and the exploration of space; however, we feel that the broad general support of ground-based astronomy should continue to be the responsibility of the NSF. NASA has in the past supported certain ground-based facilities and will continue to do so in the future after coordination with other Government agencies to avoid duplication. The NASA funds available for the support of ground-based astronomy can support only a fraction of those new ground-based facilities which do one or more of the following:
>
> 1. Contribute directly to understanding the results from the space program.
> 2. Assist in the conception, design, development, and testing of instruments and spacecraft,
> 3. Perform the exploratory and basic research necessary to guide the planning and evaluation of scientific missions and experiments in space.

I would like to interpolate a little more specifically. As you know, our original exploration of space will certainly be, as far as direct exploration, confined for some time to the solar system and particularly to the Sun, the Moon, the planets, and in the early stages to Mars and Venus. It is quite obvious, therefore, that the Space agency has a special interest in the astronomy of the planets, a subject which has engaged the interest of a few astronomers, but has not been a sufficiently popular subject to attract a large number of people. We have, therefore, felt it necessary to stimulate increased interest in the astronomy of the planets.

In the second place, the astronomical observatories enable the observation of the stars outside the Earth's atmosphere, and in order to make astronomical measurements of the wavelengths which do not get through the atmosphere, the extreme ultraviolet and so on, it is necessary for us to support considerable development of instrumentation in those areas which are not ordinarily done in connection with ground-based astronomy.

I think these two specific illustrations may make the general statement a little more intelligible.

In summary, the area of astronomy, certainly a fundamental scientific discipline, illustrates the need for both broad support on all the frontiers of astronomy by NSF, and support of specific areas of astronomy by NASA in order to accomplish its mission.

I would like to turn now to another realm of mutual interest to NASA and NSF, that of graduate training. This also is an area that I believe is of considerable interest to your committee because of the educational problems facing the Nation. NASA has had a strong feeling or responsibility to assure the availability of highly trained scientists and engineers required for the successful conduct of the space program.

As you are well aware, the space program has been a very active and dynamic program since its inception in 1958. This program was born at the time this country was facing a shortage of highly trained scientific and technological personnel and grew quite rapidly. While our present demands and future requirements involve only about 5 percent of the Nation's scientific and technological manpower pool, it was readily evident that in this new field of endeavor it was in the national interest to take immediate steps to increase the production of Ph. D.'s. One of the significant findings in this regard was the report of the Gilliland Committee of the President's Science Advisory Committee which called for doubling the production of Ph. D.'s by 1970. In view of the fact that NASA's appropriation amounted to about one-quarter of the Federal R. & D. dollars, it took as its goal the production of 1,000 Ph. D.'s annually, which represents approximately one-quarter of the increase which is generally considered to be desirable.

Benefiting by the experience of the National Science Foundation, the National Institutes of Health, and the Office of Education in their predoctoral programs, NASA developed and initiated its predoctoral training grant program in fiscal year 1962. This program is now nearing the planned level—the entrance of 1,350 new students annually into the program. It is hoped that with normal attrition, approximately 1,000 of these students will receive their Ph. D. by the time they have completed the 3 years they may be supported in the program.

This program was developed around the basic policy that NASA has for all its activities with the Nation's universities; namely, that of working within the structure of the university in a manner that will not only make it possible for NASA to accomplish its mission, but that will also strengthen the university. Time does not permit an elaboration of all of the details of this program, other than to state that grants are made to universities who in turn select the students. In addition to stipends for the students funds are made available to the university to help defray the cost of the program to the university. However, these funds are not specifically tied to the students but rather are made available to the university with the stipulation that they be used to enhance graduate education in space science and technology. That this has been a most successful program is evident by its acceptance by the universities and by the fact that it has become the model for other Federal fellowship programs.

The question has often been raised why it is necessary for NASA to have a predoctoral training program. Why can't all the Federal fellowship programs be handled by a single agency? I have already noted that NASA feels a responsibility to help develop the highly

trained scientific and technological personnel that will be required if the program is to be a success. But even more important than this is the interaction that is so essential in scientific programs between the academic community and the scientific people in the government charged with carrying on such programs. This direct interaction provides a mutual stimulation and permits the academic community to be more directly responsive to national interests.

While the selection of the students and the administration of this program is largely the responsibility of the universities themselves, the knowledge that the funds for this activity came directly from NASA, rather than from some interested but not directly concerned party, accounts in large measure for the fact that the subject matter of students theses and dissertations is a direct interest in the space program. Some examples are: "The Production of Tritium and Helium 3 by Proton Bombardment of Metals"; "Solar Origin of Terrestrial Tritium"; "Integration and Optimization of Sustained Thrust Rocket Orbits"; "Galaxy Formation in a Steady State Universe"; "Recombination Spectra of Hydrogen and Helium in Gaseous Nebulae"; to mention only a few. In addition, a number of technical publications by NASA supported trainees on space related subjects have already appeared in the scientific journals.

This program is still in its infancy inasmuch as the initial grants which covered only 100 students are just being completed. We have been extremely gratified by the results to date. As of June 15 we have been notified that Ph. D.'s had been awarded to 68 students. Of these students, information is available as to the initial career choice of 58 of them—I should mention that NASA does not require them to join NASA or to engage in any specific branch of science, other than that it be relevant to the space program—44 have chosen to remain with the university, 33 in research and teaching and 11 on postdoctoral appointments or Fulbright fellowships. Of the remaining 14, 2 were entering employment in Government laboratories and 12 were engaged by industry.

We feel that the fact that 75 percent of these were still within the university attests to the quality of the students participating in the program; furthermore these new Ph. D's are serving to meet an urgent national need by remaining in the university to help in the training of additional scientists and engineers.

While NASA subscribes to the plural system of support, we also are cognizant of the need for interagency coordination and cooperation. I would like to describe the manner in which the program I have just mentioned has been coordinated. First, Mr. Webb and I have had a continuing series of meetings with Dr. Seaborg, Chairman of the Atomic Energy Commission, with Dr. Alan Waterman, and more recently with Dr. Leland Haworth, Director of the National Science Foundation, and with Mr. Keppel, Commissioner of Education. In addition, there have been discussions on areas of mutual interest between Dr. Newell, Associate Administrator for Space Science and Applications and Dr. Smull, Director of our Office of Grants and Research Contracts, with Drs. Spofford English, Paul McDaniels, and C. L. Dunham of the Atomic Energy Commission and Drs. Bowen Dees and Howard Page of the National Science Foundation.

Further, there is an ad hoc interagency group called the Federal Fellowship Administrators that meets regularly to exchange ideas and information on such programs. Dr. Thomas Fontaine of the NSF has taken the leadership in getting the group together, which includes representatives not only of the National Science Foundation, the National Institutes of Health, Office of Education, Atomic Energy Commission, Department of the Interior, State Department, Department of Defense, Department of Agriculture, Smithsonian Institution, and NASA. Dr. Frank Hansing who handles NASA training programs has regularly participated in this activity.

In addition, by Executive order the President recently established the Federal Interagency Committee on Education which is chaired by Mr. Keppel, Commissioner of Education, and has representatives of the interested government agencies.

Finally, there are numerous almost daily contacts among our respective staffs at the operating level.

I have gone to some length in discussing the NASA training grant program, not particularly from the standpoint of the program itself, but rather to give you a picture of the types of things that are important to NASA and also of direct interest to the National Science Foundation. Of particular importance is the manner in which we coordinate such activities. If one were to consider the support of research in the academic community by NASA or the provision of research facilities by NASA in detail, he would find that the same type of interagency coordination and cooperation was being carried on in these programs also.

To give you an example of how mission-oriented agencies—in this case, NASA—and the National Science Foundation can work together, I would like to call your attention to the joint action taken recently by NASA and the NSF in making grants to the University of Minnesota, to permit the university to strengthen its scientific and technological capability. Prior to this joint action, there had been a substantial involvement by the University of Minnesota in the space program under NASA support, and in general scientific research supported by NSF. The combined NSF/NASA action included a grant from NASA for approximately $2.5 million for the construction of a building to house the university's space science center and a grant for the support of multidisciplinary research in space science and technology.

An integral piece of equipment, important not only to the research in space science and technology, but also to the scientific programs throughout the university was a computing facility for which the Science Foundation made available to the university approximately $400,000. The announcement noted that this:

> Joint action by NASA and NSF was undertaken to encourage the development of space science and technology, to help strengthen the university in both research and the production of creative manpower, and to stimulate a strong and continuing interaction between the university and the industrial community in the region which it serves.

As it has in the past, the Federal Government must continue to recognize the individual nature of our universities. It is this individuality on the part of the university that is the very basis of their

strength and must be dealt with accordingly. Although the pattern will vary from case to case, I think this type of cooperative action that I mentioned is one that you may expect to occur with increasing frequency in the future.

As noted in the beginning of my statement, NASA believes that mission-oriented scientific agencies such as itself and the Atomic Energy Commission can be most effective in the long run if there is a strong National Science Foundation. I would like to suggest that, while the Science Foundation has underway a variety of excellent programs that have been developed to achieve success in its mission—that of strengthening basic research and education in the sciences—there are two areas that at present are believed to merit special consideration.

The need for an adequate geographical distribution of our scientific endeavors, which has been discussed so much in the present Congress, is not new. The first annual report of the National Science Foundation which was submitted to the President on November 1, 1951, states:

The National Science Foundation proposes to support basic research on as broad a geographical and institutional bases as possible.

The intellectual activity and scientific competence that is to be found centered in the Nation's universities is daily of increasing importance to our national welfare. NASA, as well as the other scientific agencies, recognizes the need for a broad national basis to carry on a program that has national significance, as does the space program. The lead, however, in developing a broad base of scientific activity should aggressively be undertaken by the National Science Foundation. I feel that the mission oriented agencies must give prime consideration to the matter of competence. I believe we would all rest considerably less easy if we felt that any region of the country was barred from developing a good idea for a superior weapon system or a superior space vehicle because it had just provided the last one. That the Science Foundation is concerned with broadening our base of scientific competence is evident by the recent initiation of their science development program which is aimed at developing additional centers of excellence throughout the Nation. NSF should be encouraged in these efforts, since through the development of a broad strong base of scientific competence will come added strength to NASA, to the AEC, the Department of Defense, and to the Nation as a whole.

The second point I would like to make relates to the ever-growing importance of science in our way of living. Scientific endeavors can no longer be left in the hands of the few but rather must be in the conscious awareness of the many. While the National Science Foundation has educational programs that impinge at all levels of scientific instruction, the support of research and training has been concentrated at the graduate level. It is believed that the growing importance of science brings with it the necessity of increasing involvement on the part of the undergraduate. This is an area in which there is too little Federal activity at present. Because of the generality of the undergraduate's interest, it is believed that this is an area in which the National Science Foundation might well make a concerted effort.

Mr. DADDARIO. Do you carry this recommendation to the National Aeronautics and Space Administration, as well, that there be more aid in the undergraduate area?

Dr. DRYDEN. Generally, we have not gone in that direction at the present time, but we talk about it quite a lot and have talked in these meetings with Dr. Seaborg and Mr. Keppel and Dr. Haworth quite a lot.

Mr. DADDARIO. Do you see your mission prohibiting aid in this area, or do you see it as the peculiar function of the National Science Foundation?

Dr. DRYDEN. In general, you can't tell what an undergraduate is going to do later on, and for that reason broad support seems more appropriate.

However, I do not know of anything that would prohibit a program of this kind in NASA.

Mr. DADDARIO. Then your recommendation really goes beyond the National Science Foundation. You believe more can be done at the undergraduate level and it is just a question of how it can be worked out, rather than a specific recommendation that NSF be the only one that does it?

Dr. DRYDEN. Yes.

Finally, I would like to state that the National Science Foundation has, in the 15 short years of its existence, made a significant contribution to American science. Its continuing growth and dedication to strengthening basic research and education in the sciences is essential to our national welfare.

Now, Mr. Chairman, I am open to questions. Dr. Newell is with me. Certain subjects I might refer to him as better able to answer in detail. Between us, we will try to deal with the questions of the committee.

Mr. DADDARIO. We are happy to welcome Dr. Newell here, too, of course.

Mr. Mosher?

Mr. MOSHER. Dr. Dryden, on page 10 where you are discussing the Ph. D. program you say:

> It is hoped that with normal attrition, approximately 1,000 of these students which will receive—

And so forth. Has the attrition been normal, so far? I realize it is fairly brief experience, but is there any reason why this program should be less than normal or better than normal?

Dr. DRYDEN. I think we have had somewhat less attrition than is common in these programs, but I don't have these figures and we only have the experience with the first 100 at this time.

Mr. MOSHER. There is no reason to believe that it would be poorer than normal?

Dr. DRYDEN. I wouldn't think so. There is certain motivation about the space program that perhaps offsets some of the other attrition. I don't know.

Mr. MOSHER. Getting back to the point that Chairman Daddario was just asking, this concerted effort that the National Science Foundation might make at the undergraduate level, in what form do you think that might best be—assistance to individuals?

Dr. DRYDEN. No, we ourselves, as you know, pioneered in the policy of recognizing first that people usually don't go to college more than 100 miles away from home, there are a lot of good people in all parts of the country, that the administration is a lot simpler if you let the university pick its best people—it doesn't have to set up national committees, hold examinations. It knows from its own experience and its own record who the fine students are in that particular town, and we have rather preferred the system that we have worked out of having the universities select the best people, determine what fields they are going to award fellowships in, and so on. We think it might be a more effective program if it were handled in this way, rather than giving money to an individual who then chooses to go to one of the first 20 schools.

Mr. MOSHER. Which he probably would do.

Dr. DRYDEN. He would try to do. Not all of them would get in. Don't misunderstand me. I think the other type of program is a good one to have nationally, of recognizing bright students, but I don't think we ought to put all of our effort in that direction.

Mr. DADDARIO. I take it from your remarks that you recommend this program in balance with the others?

Dr. DRYDEN. That is correct.

Mr. DADDARIO. Mr. Roush?

Mr. ROUSH. Dr. Dryden, I want to express my appreciation for your statement that special consideration should be given to geographical distribution of our scientific endeavors. I would agree that the National Science Foundation should take the lead; I think they have taken the lead, although I believe in recent years there has been a tendency to pull the Foundation slightly away from their original admonition of Congress that consideration be given to geographical distribution. I would question and wonder about one of your statements, and that is the statement that you feel that the mission-oriented agencies must give prime consideration to the matter of competency. In the area of development and procurement——

Dr. DRYDEN. Yes, in the area of development and procurement.

Mr. ROUSH. I would agree with this part of it. In the area of research, I do not think this is as much a consideration.

Dr. DRYDEN. It is still an element of consideration, but it doesn't have the same degree of sharpness. If you have got to fly a rocket next month, you have got to find a fellow who can build a rocket.

Mr. ROUSH. In the area of basic research is it possible for a mission-oriented agency to pay a little more attention to the matter of geographic distribution?

Dr. DRYDEN. Yes, although still I think you gentlemen would be the first ones to criticize us if we put our money away on things that are obviously incompetent.

Mr. ROUSH. That is true.

Dr. DRYDEN. So competency is still a factor, but I agree with you that the relative weight, so to speak, of the various considerations that enter into the placing of contracts does not put this as high as it does in the development contract.

On the other hand, we don't want to support incompetent activities, either.

Mr. ROUSH. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Brown?

Mr. BROWN. I would just like to offer one line of thought here, Dr. Dryden. Your statement is replete with a description of science and scientific education and basic science and broad science and so forth. Yet it seems to me, as it has in many of the other statements, that basically you are referring to the physical sciences and engineering.

Dr. DRYDEN. It does not intend to, because the life sciences are also involved, although the principal agency in Government supporting the life sciences is the National Institutes of Health, of course.

Mr. BROWN. This is the point which I want to make clear—when we use the term "science" in these papers, that we are talking about physical science, life science, and social science; that science is not restricted.

Dr. DRYDEN. That is the intent; yes. We have some projects which would be called social science; very few, but some.

Mr. BROWN. I recognize in an agency such as NASA the opportunities to support social science may be somewhat limited. But when we are talking about an agency such as the National Science Foundation, which has a role in filling out the total pattern of science, we must consider these other things. We must secure proper balance for them, particularly where the mission-oriented agencies are devoted so strongly to particular areas.

Dr. DRYDEN. And I think there is such a thing as engineering science, although some of my friends think that is a contradiction in terms. But there is a variety of science called engineering science which is easily recognizable and distinguishable from technology.

Mr. BROWN. I am becoming more and more concerned that, with the proliferation of science, somewhere we become concerned with the way human beings can assimilate the results of science. Whether you call this concern a scientific concern or a social concern or a social science concern, I am not particular, but it is extremely important that we be able to make a proper connection between the ability of human beings to handle this knowledge and the generation of the knowledge itself.

Dr. DRYDEN. Nothing I have said is implied to indicate any lack of support for the humanistic side of life. I am very much interested in that personally. That doesn't happen to be the particular subject this morning.

Mr. BROWN. There is, of course, and I think should be, a strong interaction between the humanities and science.

For example, I think there is nothing more humanistic than knowledge of the broad field of astronomy. But as you indicate, NASA is not so much concerned with this aspect. However, I would like to have on the record wherever possible clarification that the National Science Foundation has a broader responsibility than purely physical science——

Dr. DRYDEN. I agree.

Mr. BROWN. And engineering, and that it may be extremely important that we move further in the direction of the social sciences, that is, the nonphysical sciences, in a broad sense.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. What are the mechanics of coordination in basic research between NASA and the National Science Foundation?

51-204—65—vol. 1——16

Dr. DRYDEN. Exchange of information on proposals submitted and the actions proposed.

Mr. CONABLE. Do you have a formal setup for doing this?

Dr. DRYDEN. It depends on what you call formal. We do exchange lists of proposals that are periodically assembled. When proposals come from a university, we like to know whether other agencies have received the same proposal and, if so, whether they are interested and what they propose to do with it. This is largely done by telephone and personal contacts, largely done by telephone, rather than what you might call a formal written procedure.

Mr. CONABLE. You don't have to formalize the arrangements?

Dr. DRYDEN. I think, as a matter of fact, the members are probably interested in one of the formal efforts to do this through the Science Information Exchange. NASA has cooperated in the provision of input concerning research and progress since the exchange was established. Figures compiled by the exchange indicate that NASA furnished information on 793 projects in 1963, 696 in 1964, and 338 in the first half of 1965. Under terms of our agreement with them we provide a complete list of research grants and contracts awarded.

With this information in hand the exchange queries the research investigators directly for specific information relating to work that they are planning to do. The recent agreement between NASA and the Department of Defense to more effectively exchange information on current research and technology programs has resulted in a standard reporting form by both agencies to facilitate machine processing, and I have seen these books in various fields which enable us to run down exactly what is going on in the other agency in any particular area. Dr. Bisplinghoff advised the exchange in April of this year that his office will expand the coverage of NASA-sponsored work in the information pool, but that recognition must be given to the fact that a sizable proportion is in a category which does not lend itself to dissemination for a general audience. That is a result of the NASA-DOD agreement to exchange information on research and technology programs. SIE will be provided information automatically in 1966, and during the interim period information will be reviewed manually in order to increase the coverage of NASA programs in the SIE files.

Mr. CONABLE. Does the initiative for the SIE come from the OST, or where does it come from?

Dr. DRYDEN. Originally I think it came from the Smithsonian Institution who then sought support from several agencies, and they did, I think, finally get the blessing of the Office of Science and Technology. For a while it was financed by contributions from about five or six agencies. More recently it has been included in the budget of the National Science Foundation.

Mr. CONABLE. The Office of Science and Technology is supposedly a coordinating group.

Dr. DRYDEN. They are not an operating coordinating agency in the sense that you are describing. They are policy. They fix the policies.

Mr. CONABLE. How do you generate cooperation between the agencies?

Dr. DRYDEN. Policies are discussed in several places; the Federal Council of Sciences and Technology, which is one of the agencies affiliated with the Office of Science and Technology, consisting of

Federal administrators, the President's Science Advisory Committee, consisting of outside people, and the Office of Science and Technology work on the policy formulation. They, for instance, as I say, took an action supporting the activities of the exchange in recommending that the National Science Foundation accept responsibility for its budget, in the interim providing for it by requesting several agencies to contribute, with the approval of the Bureau of the Budget.

Mr. CONABLE. I don't know whether I make myself clear. It seems to me in both talking with AEC and NASA, with respect to their relation with the National Science Foundation, that much of the discussion seems to involve picking up a phone and talking with somebody. This is fine, but how do you know somebody is doing that? Doesn't somebody oversee the whole thing?

Dr. DRYDEN. I don't know how to describe this. There are literally thousands of these respective proposals and there is no point in running these into a central point and having somebody who knows nothing about the field pass judgment. What you try to do is to have the various people at the operating level deal with the proposal. There is general oversight of the process by the Office of Science and Technology, and there are such activities as we have described of trying to obtain standard forms so that the information can be processed by a machine, and anybody involved would get a complete listing, which is indexed, by which he can look up the activities of an agency in any particular area.

Mr. CONABLE. You do not conceive that more operating coordination is necessary, then, than just the general oversight provided by OST and the cooperation that is generated within the various agencies on the same level?

Dr. DRYDEN. I don't see how to do this without multiplying a tremendous amount of paperwork which is of no value to anybody as far as I can see—daily, project by project, so and so telephoned this man and made this decision. Monthly we exchange lists of proposals that are before us; not actions completed, but things which have been proposed, so that if the proposal is on three desks it is known, and then those people get together and see who is interested in it. We don't want to get two people trying to support the same proposal.

Mr. CONABLE. That is all, Mr. Chairman.

Mr. DADDARIO. What you are saying is that even though there is no log kept, you know from experience that a great deal of communication goes back and forth. You are satisfied that this is the way to get the job done?

Dr. DRYDEN. Yes. I believe in the use of the telephone. It isn't always necessary to have large volumes of paper.

Mr. DADDARIO. We had testimony yesterday that this was probably the most fruitful exchange, the informal part of it.

Mr. Vivian?

Mr. VIVIAN. I would be glad to hold my questions if you would like to go on to the next witness.

Mr. DADDARIO. No, why don't you go on for 5 minutes or so?

Mr. VIVIAN. I would like to ask a question which I have asked of several other agencies. I am personally desirous of maintaining a multiple review of scientific proposals, among the agencies which are in a position legally to review and evaluate proposals, so that an in-

dividual submitting a proposal does not find himself running against the prejudice of an individual person.

Dr. DRYDEN. I think there is nothing worse than to have the decision made by one person.

Mr. VIVIAN. I am sure this is the view of a great many people in the scientific field.

Dr. DRYDEN. Yes.

Mr. VIVIAN. On the other hand, along with this opportunity runs a certain responsibility and that is to allow a split in the financial resources to each of these agencies along some pattern so that while there is a division of support, there is also a policy of splitting the funds. I am curious to know the areas in which you regard yourself as having overlap with the possible functions of NSF, which in your agency must be very great. What kind of policy establishes the split in funds; that is, what guidelines do you follow as to what should go to NASA and what should go to NSF?

Dr. DRYDEN. This is determined by the operative process of the executive branch and the Congress. This is the way it comes out.

Mr. VIVIAN. Congress has a certain degree of respect for the recommendations of the Bureau of the Budget, in some places more than others, and I am curious to know how this policy is established within your own operations. Do you make a recommendation, for example?

Dr. DRYDEN. We make a recommendation as to the amount of money in specific general fields that we think is required for supporting research and technology in connection with our mission. We do not feel we have a mission primarily to support universities. We have a job to do, and there are certain areas that are necessary to our job. In materiels, we just don't support materiels research. We want materiels included in rocket case. This fixes a certain general area.

I think a research man can be free in his research while working in a general field. There is no conflict. This is directed in a fashion in the sense that the mission agencies say, "We want you to work," or "We want people who are interested in working with tungsten, or molybdenum, to make us proposals," and if they fit in with the job we have to do, we try to give them support. I don't think we have any funds allotted—in fact, most of our funds are in the pocket of a program manager who has a job to get done, and it is his decision whether he gets the job done in industry or whether the nature of the job is one that he can take to a university, and certainly one of the things that we avoid is trying to put up a request for proposals to be bid on by university and industry. This doesn't make any sense to us, at all. Now, in general, our university proposals are unsolicited proposals. They are not requests from us to bid on anything. We want people who are interested in a certain field that they think is of interest to us, and we do give certain guidelines as to the kinds of areas that we are concerned with, to come to us with proposals. Then the program manager in this particular area decides whether this is a thing which helps him get his job done. This is the rationale behind any mission-supported agency. We want to carry out the mission in such a way that it strengthens the institutions with whom we deal. We would like to get this research done in such a way that it fits in then with the motivation and the practice of universities.

Mr. VIVIAN. I have just a brief comment on that. On page 9 of your testimony it says:

> * * * need for both broad support on all frontiers of astronomy by NSF, and support of specific areas of astronomy by NASA in order to accomplish its mission.

On page 10 you refer to the fact that:

> NASA's appropriation amounted to about one-quarter of the Federal R. & D. dollars, and it took as its goal the production of 1,000 Ph. D.'s annually, which represents approximately one-quarter of the increase which is generally considered to be desirable.

Then on page 11 there are further remarks on the split in programs. I have no objection to the split. I am trying to find out what guidelines govern the split.

Dr. DRYDEN. The Ph. D. program was an executive branch decision extending from the President's Science Advisory Committee, and the various agencies were asked to see what they could do in various parts of this program, to make up the total that it was desired to accomplish. NASA was successful in getting the funds; some other agencies were not. So in this particular instance the process that I have described to you, going through various committees of the Congress and so on, did not lead to a uniform action of the Congress on the executive branch proposal to increase the number of Ph. D.'s by 4,000 a year. But that was done as a concerted action.

Mr. VIVIAN. In other words, one might conclude that NASA made this conclusion itself as to supporting one-quarter; but you would say that it was really an administration decision?

Dr. DRYDEN. That is correct.

Mr. DADDARIO. In that regard how do you look at this program of producing 1,000 Ph. D.'s annually; is it one that will go on as long as the space program is in existence?

Dr. DRYDEN. I would doubt that it would remain at that level. In fact, if this process which I mentioned operated in such a manner that the resources of the Science Foundation were greatly expanded, then I can see some reason why we would not feel it necessary to go in as heavily.

Mr. DADDARIO. Then it does get back to Mr. Vivian's question. This is one area where in the production of Ph. D.'s you are not necessarily mission oriented; you have a tenuous relationship, but not a direct one?

Dr. DRYDEN. This is more than just a tenuous relationship, we need some relationship, we want some part of that program. The size of the program is certainly a matter which is subject to review and adjustment from time to time. In this particular instance I would feel that if there were some way by which we could get—excuse me a moment—I lost my train of thought.

I was going back to say that NASA came on the scene, you remember, with $300 million in the first budget, and has gone to $5 billion very quickly, and did draw a share of the existing manpower. We don't know that very much diversion can be proved. Actually, the Defense Department programs were going down, at a time the NASA program was growing, but we did feel some re-

sponsibility, having greatly increased the demand to do something about its replacement. Therefore, we were quite willing to cooperate in this executive decision and do our share in doing something about it.

Mr. DADDARIO. I gather then that if the Gililland Committee's findings which involve the doubling of the production of Ph. D.'s by 1970 are sound, and if it were to be decided that this is a figure that must be obtained, and if it were to become a greater responsibility of the National Science Foundation to reach this objective, and if the funds were then provided to do so, there would be no reason at all why to this extent NASA would allot funds for one-quarter of the Ph. D.'s?

Dr. DRYDEN. That is correct. The size of the program, I think, is subject to review and adjustment in the light of what is being done throughout the Government.

Mr. DADDARIO. The executive branch determined it would like to double the number of Ph. D.'s, and since you had the funds available, you were able to do it where other agencies were not?

Dr. DRYDEN. That is correct.

Mr. VIVIAN. I have a brief comment and then I would like to pass on to the next person, Mr. Chairman, since my other questions might take a considerable period of time. I think one of the merits of multiple support might be evidenced by your remarks on page 11: "We notice it has become a model for other Federal scholarship programs." Although some of the other agencies might disagree with you as to who started it, I think it is true that it is advantageous.

Dr. DRYDEN. We did not invent this process. I think it probably was done in NIH earlier than in NASA.

Mr. VIVIAN. Perhaps the statement wasn't quite as positive as it might seem from this remark.

Dr. DRYDEN. But very soon after we adopted this, it was adopted in other agencies.

Mr. VIVIAN. And I believe, in the paragraphs below, on page 11, you are saying in part the following: That when a given agency has relationships with a number of members of the teaching staff of, say, a given university, that person tends to turn out students who themselves are interested in your programs, who might otherwise go on to other areas. It is not that they are necessarily forced into your zone, but simply that they develop an interest; and it stays with them afterward?

Dr. DRYDEN. They have an opportunity to develop an interest in it, and we think we will get a sufficient number for our purposes without distorting the whole picture because we place no requirements that they come into our program.

Mr. VIVIAN. I saw this very strongly in the past in several universities where even though very attractive programs were offered at fairly good salary rates, where all the considerations were favorable, it was very difficult to turn persons from endeavors of a lifetime into a totally new field, even though the field itself was attractive. You have to develop graduate students from the beginning.

Dr. DRYDEN. You have to begin young. We found that, in the old NACA, rocketry and jet development was not being taught in univer-

sities at all. We had to catch the students and train them ourselves.

Mr. DADDARIO. Dr. Dryden, I am pleased you were able to come this morning. We hope we will be able to send you additional questions which we don't have time to ask you today.[1]

Dr. DRYDEN. I will be very glad to provide the answers.

Mr. DADDARIO. Thank you, Doctor.

Our next witness is the dean of the Graduate School of Public Administration of Harvard University, Dr. Don K. Price. We are very happy to have you here this morning. The members of the committee know that you have been extremely helpful to us in the past, and we are anxious to listen to you on this subject.

STATEMENT OF DR. DON K. PRICE, DEAN, GRADUATE SCHOOL OF PUBLIC ADMINISTRATION, HARVARD UNIVERSITY

Dr. PRICE. Thank you, Mr. Chairman. I think, since my statement would probably take a bit longer to read than the amount of time you suggested, I will abbreviate it fairly considerably in the presentation and leave the text for the record.

(Dr. Price's prepared statement follows:)

PREPARED STATEMENT BY DR. DON K. PRICE

It is a pleasure to take part in this series of hearings, Mr. Chairman, because it seems to me that your subcommittee, in undertaking to review the record of the National Science Foundation, is opening up for further study one of the most significant political problems of our time: the way in which science and Government are interacting.

You suggested that I might wish to comment on the role of the Foundation, especially in relation to other agencies of Government. This covers, of course, the ways in which the Executive Branch develops its scientific policies, and the relation of the various programs of applied and basic research throughout the Government.

The Foundation, I hope most of your witnesses will agree, has been a remarkable success. It is the occupational bias of a professor to view with alarm rather than to point with pride, but today I have to face the fact that the Foundation has been a most successful political invention. But success, in affairs of state, is never a permanent thing: new problems arise for any institution just because it is successful. And the problems that we can see ahead in the Government's support of science and related educational activities warrant a careful and critical review of the principles on which the Foundation was conceived 20 years ago, 5 years before it was actually brought to birth.

Those 5 years were spent—an impatient observer might say, wasted—in debating all possible aspects of the proposed Foundation's organization and program. The main issues seem to me, as I look back on them, to fall in two categories. One was the problem of the relation of science to political authority; the other was the relation of basic science to applied science.

Of the two, the relation of science to political authority was the more fundamental, at least from the point of view of a political theorist. It caused most of the bitter argument, and led to President Truman's veto of the first bill that was passed by Congress in 1947. Could science get large-scale Federal support without running the risk of political interference? And could any type of organization be invented to prevent political interference without giving a scientific elite a privilege and irresponsible position in our constitutional system? After President Truman vetoed a bill that would have given undue authority and independence to a part-time board, one might well have thought the problem a hopeless one.

Yet in retrospect, this particular problem was solved so easily, and so much to everyone's satisfaction, that today the issue almost seems a phony one. By contrast, the problem of the relation of the Foundation, with its basic research programs, to the Government's program of applied research, and to the potential

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

new programs of research and of education, seems a much more difficult one, even though of less theoretical significance.

Perhaps the original trouble, in the 5 years after the presentation of Dr. Bush's report, arose because many scientists confused the proposal of a National Science Foundation with the idea that the Government should continue in peacetime, for civilian purposes, the type of large-scale support of applied research that had produced the new weapons and weapons systems of the war. That was not the main point of the Bush report, which argued for the support of basic research in independent institutions. But many others had in mind a broader and more practical program of Government support for science. And that idea raised in the minds of many American scientists the bogey that had dominated the debates among Western European scientists during the 1930's: the twin Marxist doctrines that science ought to be supported only for its social utility, and directed by political authority.

If the National Science Foundation in practice had so little difficulty with the issue of science and political authority, it was in part because this Marxist bogey had no relevance to the Foundation's primary purpose, nor that of the Bush report. In the first place, the proposition that science should be supported for its practical applications may have been identified with Marxism by European theoreticians, but in the United States it was an old tradition, dating back at least to Jefferson and Franklin, and honored in practice by every land-grant college and appropriation committee. What the Foundation was trying to do was to provide for the first time for a good measure of support of basic science—science which could not, or should not, be connected at the outset with a particular practical purpose. If you define radicalism as any new Federal spending, the Bush report was very radical indeed. But from the point of view of socialist theory, it must have seemed quite a reactionary document.

But these categories of radicalism and conservatism do not fit American politics very well. We are not nearly doctrinaire enough—I should say, we are too sophisticated—to make that possible. We are quite capable of expanding governmental activity and at the same time increasing the freedom of citizens and of private institutions, and this turned out to be true of the work of the National Science Foundation.

It should have been clear in theory, between 1945 and 1950, that this could be done. There are of course profound connections between a nation's politics and its religious thought, its system of education, and its basic science. But it is still possible for a nation—in particular, for the United States—to separate church and state, and maintain schools and universities that are free of political control even though supported by taxation.

But theory is never as convincing as a good experiment, especially in politics. And what we failed to learn from theoretical debate, the Office of Naval Research demonstrated for us. While many scientists were arguing that Federal grants could not be given, without destroying academic freedom, through any agency that was not thoroughly insulated against the administrative discipline of the President, the Navy did it. If a department dominated by a military chain of command, and fully subject to the Commander in Chief, could give grants for basic research without dictating to the scientists, it was obvious that the kind of freedom we sought did not depend on the details of that level of administrative organization. It depends instead on a consensus—throughout the Congress and the executive branch and the country as a whole—that our universities and research institutions should not be directed, in their scientific and scholarly concerns, from Washington, even if they needed and were given financial support. The corollary of this consensus is that many policy issues affecting science and the universities—questions like magnitude and types of financial support, the principles of its distribution, and the terms of accountability—are not issues that can be determined on scientific principles, nor by scientists. And these have to be dealt with through the normal system of political responsibility.

It is encouraging to me to note how well this kind of separation of roles—almost an informal kind of separation of powers—has worked out since the Foundation was established.

The basic procedural safeguard for the independence of scientific institutions from centralized bureaucratic control is provided not by the Board, and not by the statutory divisional committees, but by the subordinate advisory panels which review applications for the support of projects. These panels are similar in function and purpose to those that have been set up by other Federal grant-making agencies, within a great variety of departmental and agency structures.

It has become virtually an established political principle that there should be, in academic and scientific fields, no subsidization without representation.

On the other hand, we have seen the higher statutory structure of the Foundation, which was originally conceived as an elaborate system of checks and balances, evolve into something more like normal administrative machinery on normal administrative principles. Many scientists are good at administration even if they feel a professional compulsion to depreciate it. As the workload of the Foundation has increased, its structure has been adjusted to let it get its job done, and deal with its policy issues, and less attention has been paid to the original conception that 24 eminent scientists on the Board should themselves make the grants, and that the Director and his administrative staff should be kept in the background. The various steps that have been taken (by statute and reorganization plan) to permit the Board and its executive committee to delegate functions, to alter the statutory pattern of subordinate divisions, and to raise the status of the Director, all seem to me a sensible series of developments. Even more important, perhaps, is the change in the Board's own view of its role. It began by organizing itself into committees mainly to correspond with particular fields of science. More recently, it has taken a broader view of its policy role and set up its internal committees on more general aspects of the Foundation's business—such as its substantive scientific programs and their relation to national policy, the administrative aspects of its relation to grantees, and its long-range plans, especially with relation to other Government programs.

This new emphasis on policy may seem to some critics an effort to lock the barn door after the horse has been stolen. One of the most frequent complaints about the Foundation used to be that it failed to do one of the main jobs that its basic act gave it: the job of developing a national policy of basic research and scientific education, and evaluating the performance of other Government agencies with respect to that policy. To such critics, the creation of the President's Science Advisory Committee and the associated Office of Science and Technology constituted a judgment that the Science Foundation had failed.

This seems to me a fallacious criticism, I would acknowledge—indeed, I would heartily agree—that the Foundation had failed to meet the expectations of some of its original supporters, who had been encouraged by the language of its act. Nevertheless, I would argue that the Foundation's role in policy has not been diminished by the reorganization plan that transferred certain of its coordinating functions in 1962 to the OST. Indeed, it seems clear to me that the existence of the Office of Science and Technology gives the Foundation a much greater range of potential policy influence than it could have had without that Office.

Policy is not something that can be divided up neatly, even by statute, and assigned to different agencies. If it means—as I think it does—the broader aspects of any Government agency's business, the aspects that affect the affairs of other agencies and excite the attention of the public and the Congress, then it follows that it cannot be defined in advance and assigned conclusively to anyone. Within the executive branch, the President is bound to be interested and involved; within the Congress, any important policy will certainly demand the attention of both a legislative committee and an appropriations subcommittee, and probably more than one of each.

When the Office of Science and Technology was formally given responsibilities for coordinating top policies, this did not freeze out the Foundation. To be technical about it, the pertinent passage in the reorganization plan transferred from the Foundation only "so much of the functions" of policymaking as would enable the Office of Science and Technology Director to advise and assist the President. Since the ability to advise the President depends more on the President's receptivity than on any statutory formula, it does not seem to me that very much of that unmeasurable and impalpable substance was necessarily taken away from the Foundation. Regardless of the technical language here, the ability to influence policy is inherent in all agencies of the Government, and indeed in all free citizens; it depends more on what one knows and what one can do than on any formal authorization. And as long as the Foundation has the ability to make grants wherever they will best advance science, and the duty to collect and disseminate information on scientists and their research work, it has ample opportunity to help develop science policy. It could not, as a practical matter, exercise authority over the scientific programs of the other departments and agencies, even with statutory authorization to do so. But now its information and its advice, to the extent that they are persuasive to the Office of Science

and Technology and the President, have an enlarged range of potential influence.

This brings me to my second main point. While I think we were too much worried a couple of decades ago about the relation of science to political authority, we were not worried enough about the relation of basic science to applied science, with all its impact on Government programs. We are reminded how much more complex this problem is than most people could foresee in 1950 if we read again the statutory language by which the Foundation is authorized and directed, "at the request of the Secretary of Defense, to initiate and support specific scientific research activities in connection with matters relating to the national defense * * *." The idea back of that language seems rather quaint only 15 years later. Could we really ever have expected that Defense would need to look to the Foundation to run its research program for it. It reminds us how much more complex our national scientific programs are today than we would then have expected. Who would then have thought that by 1963 the National Institutes of Health and the National Aeronautics and Space Administration would each have surpassed the Foundation in the amount of basic research support awarded to universities? On the other hand, who would have expected that the Foundation, which was created to support basic research and forbidden by law to operate its own laboratories, would be in charge of the national program of weather modification, and actually running a project like Mohole?

Clearly, we are going to be engaged, as a nation, in more and more scientific research, and more and more technological programs, and some sense of policy, some general approach should guide the future decisions of the Government with respect to the relation of basic and applied research programs.

In this brief testimony, I can only outline what seem to be the desirable lines of future policy.

First, I see no point in the notion of a single Department of Science. It seems to me as useless to try to segregate science as to allocate responsibility for thinking about policy; both are parts of the job of every agency of Government.

Second, I would not try to prohibit any agency that supports applied research from supporting a small proportion of basic research along with it. The borderline between "basic" and "applied" is impossible to police. But more important, it seems to me highly desirable to have basic research supported by a variety line between "basic" and "applied" is impossible to police. But more important, of sources. An applied research program, by all scientists' testimony, is more fruitful if a certain amount of basic research is mixed with it. And from the broader point of view, it is healthy to have a multiplicity of sources of support for basic research: this pluralism, far more than any procedural rules or committee structure, is the fundamental protection for scientific freedom.

Third, I should think the National Science Foundation would do well to concentrate on its original purpose, in the main, of support for basic research and related educational activities. The Foundation is the Nation's main means for insuring that the varied purposes of agencies with particular programs do not pull science away from the lines of development that its own leaders think most fruitful. I am not particularly worried, as the system works now, that universities will seriously distort their programs of research and education in order to get Federal grants. As long as one of the major granting agencies exists to serve the purposes of basic science in general, the special-purpose agencies will have much more incentive to help support basic research without defining the scope of their interests too narrowly. There is a competition for quality projects among Government agencies, it seems to me, that helps to protect the interests of the scientist that competition might be much less effective if the Foundation did not exist to set a continuing example of regard for freedom of research at its highest level.

By this, I do not mean that I would wish to prohibit the Foundation from engaging in any applied research, or from undertaking any major projects in special fields. Obviously there may be special opportunities for the advancement of science that can be met in no other way, and that would justify exceptions. But to undertake very many programs of this kind would change the Foundation, I fear, for the worse, and alter its unique sense of mission. Moreover, it would require changes in its internal organization that might handicap its basic purpose. A major operating program will tend to demand more of the energy and attention of any executive than will the general run of smaller projects. In this case, this incentive may work against the Foundation's fundamental purpose.

A main argument for the support of basic undirected research is that the small research project may have unforeseen results of incalculable importance, while the large development project will tend to confine itself to the purposes for which it was set up. The more large programs or projects of an applied nature the Foundation takes on, the more, I fear, will its top staff be obliged to neglect the unique purpose for which it was established. I think that Dr. Waterman was very wise, a few years ago, when he recommended that the Foundation not be given a new statutory mission for administering an oceanography program, and coordinating the oceanographic activities of other agencies, on the grounds that such a mission was not compatible with the pattern of organization, and the type of staff members, through which the Foundation carried on its basic science program.

Science is so pervasive a part of modern life that I do not think that in general we should try to organize departments of Government according to their use of particular fields of science or technology. It still seems to me that each major department should include the several activities that are useful in accomplishing some broad public purpose, and that science and technology should be thought of as essential, though subordinate, means to its ends.

But basic science, like education, is an all-important kind of social overhead. It cannot be tied exclusively to any particular social purpose without being limited and distorted in its nature. It deserves a special and central place in our executive organization, for what it does can have powerful effects on nearly everything else in modern life. And it must work by unusual procedures, since it depends for its effectiveness not on what goes on within its own hierarchy, but on what it can do for a multitude of independent institutions.

If that is the purpose of the National Science Foundation, I am inclined, as I think about its future, to be less concerned about the closeness of its relationship to great agencies with technological programs like the Atomic Energy Commission and the National Aeronautics and Space Administration, than about its relationship to the basic research program of the National Institutes of Health, and to the rapidly expanding support which the Office of Education is giving to universities, and to the future program of the proposed National Foundation on the Arts and the Humanities. The other operating departments and agencies must give priority to their own special purposes, as they consider how to make use of the research services of academic institutions. But these few have a joint concern for the total health of our system of higher education that must link their interests closely in the future. How that link is to be forged I would not try to recommend or to predict today; in the United States, we can devise a great many ways to develop unity of policy when we wish to do so, and an equal variety of ways to guarantee diversity and independence. The creation of a single Department is not always the best way to approach an important purpose, though it may be.

At any rate, the most obvious lesson of the 15 years of history that we are reviewing is that it is not always easy to predict the future. That salutary lesson should excuse me if I end on a note of uncertainty. I thank you for the opportunity of meeting with you today.

Dr. PRICE. It is a pleasure to take part in this series of hearings because it is opening up for further study a subject in which I have been very greatly interested. You suggested that I might wish to comment on the role of the Science Foundation especially in relation to other agencies of Government. This, of course, involves the ways in which the executive branch develops and coordinates its scientific policies.

The Foundation, I hope most witnesses before you will agree, has been a considerable success. It is the occupational bias of a professor to view with alarm more than to point with pride, but I do think I must face the fact that the Foundation has been a highly successful political invention. But in matters like this success is never permanent. New problems arise for any institution just because it is successful, and the problems that we see ahead warrant a very critical review of the principles on which the Foundation was conceived 20 years ago, 5 years before it was actually brought to birth. Those 5

years were spent, or maybe wasted, debating all sorts of issues of organization and program. They fell into two categories it seems to me. One was the problem of the relation of science to political authority, and the other was the relation of basic science to applied science.

Now, the relation of science to political authority seems to be a political theorist, to be the more fundamental issue, and it caused most of the argument. It caused, of course, President Truman's veto of a bill that would have given undue authority and independence to a part-time board. And yet in retrospect this particular problem seems to have been solved so much to everyone's satisfaction that the issue today seems almost a phony one. By contrast, the relation of the basic research programs of the Foundation to the Government programs of applied research and to the potential new programs of research and education seems a much more difficult one.

Perhaps the trouble came because scientists were worried at the end of the war that we might be trying to continue wartime organization of science for civilian purposes, disciplining science and controlling it along the lines of Marxist philosophy. That philosophy included two ideas, first, that science ought to be supported for its social utility, and second, that it ought to be directed by political authority. The postwar debate seemed to be about these ideas. Much more than about the idea that Dr. Bush had actually proposed. Of the two notions which in the debates of that period tended to be identified with Marxism, only one was really uniquely Marxist. The proposition that science ought to be supported mainly for its social utility was one of the oldest American traditions, going right back to Jefferson and Franklin, and I think this proposition needs to be separated very carefully from the question whether science should be politically controlled.

We are not doctrinaire enough—we are too politically sophisticated—to connect those two ideas: it has instead proved possible to expand governmental activity in a field like this and at the same time to increase the freedom of citizens and of private institutions, and I think this has been true of the work of the Science Foundation.

Now, it could have been and was argued at the time in theory that we could indeed support science, including basic science, without controlling the internal administration of universities. The theoretical arguments, as is often true, did not impress anybody very much. But what we failed to learn from theoretical debate the Office of Naval Research came along during the period after President Truman's veto of the original Science Foundation bill and demonstrated for us, and it was quite clear that if within a department under a military chain of command we could give basic research grants to universities without interfering with their freedom, it was quite clear that a civilian agency could do so and that the precise details of its top organization were not all that fundamental.

The basic protection of freedom did not turn on these administrative details, but on our national consensus that our universities and our research institutions, even if they needed and were given Government financial support, should not be directed in their scientific and scholarly concerns from Washington.

This consensus is in a way the opposite side of the coin from the belief which is I think equally fundamental, that the major policy is-

sues affecting science and the Federal relation with universities, questions like the magnitude and the types of financial support and the principles of its distribution and the terms of its accountability, are not issues that can be determined on scientific principles nor by scientists or academicians. They have to be a part of the normal system of political responsibility. And the distinction between the two types of issues is not an impossible one for us to work out in this country. It amounts almost to a new kind of separation of powers in this new set of administrative relationships.

If we try to apply these general observations to the Science Foundation itself, it suggests that the best procedural safeguard for the independence of scientific institutions from political control has not been provided primarily by the Board of the Science Foundation, which was expected to be the great safeguard at the beginning, not even by the statutory divisional committees, but by the subordinate advisory panels which review applications for the support of projects. These panels are quite similar in function and purpose to those that have been set up by other Federal grant making agencies, most of which are not headed by independent boards. It has become virtually an established political principle that in a field like this we should not have subsidization without representation.

On the other hand, we have seen the higher statutory organization of the Foundation, which was thought of as a kind of system of checks and balances, evolve into something much more like normal administrative machinery on normal administrative principles. The original idea that the 24 eminent scientists on the Board should really make the decisions and the Director and his administrative staff should keep in the background was really not an idea that could work at the scale of business that the Science Foundation got into. The various steps that have been taken over the years, both by statute and by reorganization plan—they are beautifully summarized in the report which was prepared for you by the Science Policy Research Division—seem to me to permit the Board and its Executive Committee to delegate functions, to alter the statutory pattern of subordinate divisions, and to raise the status of the Director in ways that have been highly sensible from the administrative point of view. And moreover, they have let the Board itself adopt a more effective policy role.

When they began, the Board organized itself into committees which corresponded with fields or disciplines of science. More recently it has taken a broader view of its policy role and set up its internal committees on more general aspects of the Foundation's business—its substantive scientific programs, the administrative aspects of its relations to grantees, and its long-range plans, all of which constitutes a new emphasis on the broad policy aspects of the Board's business.

Now, this new emphasis may seem to some critics to be an effort to lock the barn door after the horse was stolen, because one of the complaints which academic critics in particular made about the Foundation a few years ago was that it had failed utterly to do one of the main jobs that its act gave it, the job of developing a national policy of basic research and evaluating the research performance of other Government agencies. And to these critics the creation of the President's Science Advisory Committee and then the later creation of the Office of Science and Technology constituted a judgment that the

National Science Foundation had failed. This seems to me to be basically fallacious. I would heartily agree that the Foundation never did much, if anything, about policy coordination and program coordination, but I do not think that the Foundation's role in policy was diminished in 1962 by the reorganization plan that transferred some of its nominal coordinating functions to the OST. The Science Foundation had simply never been able, as Dr. Waterman himself acknowledged in his testimony on that plan, to undertake this policy coordinating responsibility.

It seems to me that policy is not something that you can divide up neatly, even by statute, and put in one place or another. If it means the broader aspects of any Government agency's business, the aspects that affect the affairs of other agencies and excite the attention of the public and the Congress, I think it follows that it cannot be defined in advance and assigned conclusively to anyone. I would even say that we ought not want to do that because on problems with this range of importance within the executive branch the President is bound to be interested, and the basic decisions if they can't be made by agreement among the agencies have to be made by him and within the Congress. Any important policy will certainly demand the attention of both a legislative committee and an appropriation subcommittee and probably more than one of each. So, when the OST was formally given some responsiblities for coordinating top policies, I do not think this froze out the Foundation. To be technical about it, that pertinent passage of the reorganization plan transferred from the Foundation only—as the phrase read—"so much of the functions of policymaking as will enable the Office of Science and Technology's Director to advise and assist the President." This doesn't seem to me to have taken away very much of that impalpable substance from the Foundation. As long as it has the ability to make grants wherever they will best advance science and the duty to collect and disseminate information on scientists and their research activities, the Foundation has an ample opportunity to help develop science policy.

It never, as a practical matter, could exercise authority over the scientific programs of the other agencies even with statutory authorization, but now I think its information and its advice, to the extent that they are competent and persuasive, have an enlarged range of potential influence.

Mr. DADDARIO. Do you think that is one of the major factors involved here? Because it was a new agency, it could not in fact have exercised such control over the research efforts going on in the other agencies anyway. Therefore, it was wise to move some of that responsibility closer to the President where the necessary power and control could be generated?

Dr. PRICE. Well, a lot of my fellow students of administration like to make a lot of the argument that no one operating department or agency can very well exercise coordinating authority over other departing departments and agencies, that this can be done only from the Executive Office of the President. I think there is something to it: but it is not quite so clear as all that, because after all the State Department and the Justice Department are operating departments and agencies and they do act as the President's staff agencies. But I think

the trouble about the Science Foundation ran somewhat deeper, in two ways:

(1) It was headed by a Board made up mainly, except for the Director, of part-time people, and it is hard for that kind of a board—it is impossible for that kind of a board to be around when the specific issues come up on a day-by-day or week-by-week basis. It is impossible for them to run into the Presidents' office when they need his support on an informal and easy basis, and it is not always possible for them to make up their minds and agree on issues. So, if you want an operating agency to assume (under the President, as is essential to our constitutional system) executive coordinating responsibilities, I do not think it can be headed by a board.

(2) I think the other problem is almost equally fundamental. If the Science Foundation is going to deal mainly with basic research, and later in my prepared testimony I make something of a point of this, it has to be organized in such a way as to understand and appreciate the problems of the basic disciplines of science. This means almost by definition that it is not going to be set up and staffed so as to understand the major operational programs of the Government. It is going to be made up of people who know about physics and chemistry and biology. They are not going to be people who understand the space program and the public health program and the military weapons program. So, I think it would have distorted its whole program to have tried to staff itself up to understand the relevance of fields of science to the operational programs of these agencies. As Dr. Dryden explained so well a little while ago, I think as long as the basic decisions of the operating agencies, the mission-oriented agencies as the phrase goes, have to be made primarily on the basis of their major purpose, I do not think you can afford to let an agency set up with a basic science mission tell them what to do about their jobs.

Now, this comes back to what I think is the absolute fundamental. It seems to me that the major departments and agencies of the Government ought to be set up not to correspond with fields of science. That would lead you, whether you liked it or not, into a system in which engineers and scientists would have an edge in making the basic policy decisions. They ought to be set up, it seems to me, to correspond with major public purposes, a system of organization which lets the administrators with general responsibilities and their superior political officers make the basic policy decisions from time to time. I think this is fundamental to our system of responsibility, and from the point of view of continuous adjustment to new political needs, it is the most effective and most efficient system anyhow.

If this is true, I just do not think that an agency like the Science Foundation can be given coordinating responsibilities, even in the sense of the limited type of authority that can be exercised by staff people in the Excutive Office. Fundamentally, within the executive branch, only the President can tell the head of the Defense Department or the Space Agency, "Look, whether you like it or not, I want you to do things this way and not that way." But short of that, his staff members in the Executive Office can exercise a lot of leadership and a lot of leverage, because they are close enough to the President to have some sense of his political purposes and some sense of the

extent to which he would wish to make adjustments in an operating program for the purpose of supporting science.

I don't believe that this can be done by an agency which, like the Science Foundation, is expected to be organized along basic scientific lines and more or less insulated from the President's political leadership. That was too long an answer, I am afraid.

Mr. DADDARIO. No, it is extremely interesting. But I think we have to take into consideration, too, that as some of these shifts have taken place, some of the mission-oriented agencies find themselves short of funds for basic research. The tendency seems to be, according to the testimony we have received to date, that they look to the National Science Foundation to fund more and more basic research. I would like your ideas on this. If in fact the National Science Board operates on a part-time basis without any staff of its own, but has to look to the National Science Foundation itself for help to put together its own work and its own advice to the Director, then it is actually getting advice from the very people who are giving advice to the Director himself. Perhaps we should strengthen the Board even though some of the shift has already taken place. We find, too, that this question of staffing is a problem in OST. They have a very small staff. It would seem to me that even though they are closer to the President, they may not be as well tooled to do the job in the future as we would like. Would it be wiser at this time to begin strengthening the Board rather than to be building a larger staff in OST to do something that can, perhaps, better be done within the Science Foundation as it now exists?

Dr. PRICE. These are problems of degree that I do not think anyone can give a final answer to. My own prejudices would be that I like to keep my eye most firmly on the operating departments and agencies, because I think that is where the big job has to be done, and in general I would like to have very small and compact staff agencies and coordinating bodies. I think the OST will be very much better operating at its present size than if you quadrupled it. I am not saying now whether it should be slightly bigger or slightly smaller.

Mr. DADDARIO. They are asking for four more people.

Dr. PRICE. That does not sound frightening to me, but there is always a temptation to see these interdepartmental fields of interest and to say if we were to multiply our coordinating agencies in size we would get the job done better, and I am not sure whether that is true in many cases.

I would hate to see within the Science Foundation any organizational step which would suggest that the entire Foundation staff is not really the Board's staff. I think to set up something like a system of checks and balances between the Board on the one side, and the Director who is a member of the Board on the other, would be wrong. If the staff is not serving the Board's purpose, I think the Director ought to be asked by the Board to get a different staff.

Mr. DADDARIO. You see a danger, then, if the Board were to set up a permanent staff of its own, separate and apart from the National Science Foundation?

Dr. PRICE. I would think that would be a very frightening prospect to me. I may be thinking too much in terms of the analogy of a

private foundation in which I once worked, but it seems to me that could lead only to confusion if you started that sort of business. Should I go back to my statement?

Mr. DADDARIO. No. There is another question I would like for you to comment further on, if you feel it is necessary. As the years have gone by and as the advisory committees have performed the function which perhaps wasn't originally expected of them—to be the basic procedural safeguards, as you put it—have we through experience begun to evolve a proper working relationship between the National Science Foundation and its responsibilities to the other agencies of Government involved in research and education?

Dr. PRICE. It seems to me basically on sound lines. I would like to go back because what I said a few moments ago may have conveyed a meaning I did not intend. I would see nothing wrong about letting the Director of the National Science Foundation build up his subordinate staff to serve more adequately the purposes of these Board committees which Dr. Wenk's report tells about, which are primarily policy committees. If the present staff which accumulates most of our basic statistics in this field were strengthened with people whose interests run more to the policy content of the problems with which the Science Foundation must deal and less with the publication of quantitative statistics, that might be a very useful thing.

I happen not to know enough about the internal workings of the Foundation to offer that as a suggestion with any great confidence, but I would not rule it out at all by what I said a moment ago, that I would not like to see a separate staff apart from the regular Foundation staff set up to serve the board. I think the Director might well wish to strengthen the Foundation's staff which works on these more general problems of science as well as the staffs that serve the purposes of particular scientific disciplines because I think the very process of making these general studies has a very powerful effect on the policy processes within the Executive Office and is bound to be influential.

May I go back then to my prepared statement, and turn to the second main point, which has to do with the relationship of the basic to applied science? Here, of course, we see the greatest contrast today with what was expected 15 years ago. Today it sounds positively quaint to suggest, as one provision of the act provides, that the Foundation might at the request of the Secretary of Defense initiate and support research related to national defense. It is hard to realize that a couple of decades ago we really thought that Defense might look to the Foundation to run a considerable part of its research program for it. But then there are other equally great surprises over two decades. No one 20 years ago would have thought that by this time the NIH and the space agency would each be greater than the Foundation in the amount of basic research support to universities.

And I do not think anyone would have expected 20 years ago that the Foundation, which was created to support basic research and forbidden by law to operate its own laboratories, would be in charge of the national program of weather modification and actually running a project like Mohole. Now, this suggests to me that the problem of the relation of our basic research programs to our applied research programs is probably more difficult than the issue which was debated so

vigorously when the Foundation was set up of the relation to political authority.

I would like to make only three points about what seem to me to be the desirable lines of future policy.

First, I do not see any point in the notion of a single Department of Science. It seems to me it is as useless to try to separate science off from operational programs as anything else that is an essential support to operational programs.

Second, I would not try to prohibit any agency which does applied research from supporting a small proportion of basic research along with it. The arguments for this were well outlined by Dr. Dryden, and I don't need to repeat them.

Aside from the need for a multiplicity of sources of support, I think that it is extremely fruitful and invigorating for any applied research program to have a certain amount of basic research mixed in with it.

But third, I should think that the National Science Foundation would do well to concentrate in the main on its original purpose of support for basic research and related educational activities and not get pulled too deeply into programs of applied research. It seems to me that only as long as the Foundation concentrates on basic research will it in a sense keep the great mission-oriented agencies on their toes in their support of basic research by setting high standards of quality and competence. We build a lot of free competitive enterprise into our governmental structure, and I think this is a very good thing indeed and one of our main safeguards.

If the Science Foundation would get to be more like the operating agencies, more interested in applied research and development, I think its standard-setting function would suffer. I do not suggest by this that I would wish to prohibit the Foundation from engaging in any applied research or from undertaking any major projects in special fields. There may be special considerations that would justify such undertakings. I suppose, although I know very little about either one of them, the weather modification program and Project Mohole were justified in this way.

Mr. MILLER. Mr. Chairman, I am very happy to hear this. Isn't it true, Doctor, that there are programs such as weather modification and oceanography that do not find themselves within any one department of Government? Whom would you turn the Mohole over to? You would have competition within the Government to see who is going to do this job.

Dr. PRICE. And I think you can overdo the competition within Government.

Mr. MILLER. You certainly can.

Dr. PRICE. It is awfully easy to be a Monday morning quarterback. This is a problem where I could not, as I think back, think of an alternative I would have suggested if you had asked me at the time that it was being done. But you may remember the line in Gilbert and Sullivan "What, never; well, hardly ever." I would simply say I hope this does not become necessary too often.

Mr. MILLER. I think we join you in that.

Dr. PRICE. Oceanography I think is a little bit different. Project Mohole was a big single specific job that had to be done. I think Dr. Waterman was correct in believing that it would be unwise for the Science Foundation to be given the coordinating responsibility for the oceanography program because that seems to me to be a program not involving a single project but the opposite. Its problem is that so many agencies are in the act that the problem of devising a coordinating system is very difficult.

Mr. MILLER. That is one of its weaknesses now. There is no question of that. So far as Mohole is concerned, we conceive of it in connection with oceanography merely because we decided to drill the hole at the bottom of the ocean. If we had gone out on dry land, it would have been a different story.

Dr. PRICE. I really would not like to sit here and suggest that I am an expert on Project Mohole or know how that troublesome history could have been made better. I really do not know that story very well.

Mr. MILLER. I think that out of Project Mohole we learned a great deal. We did a little creeping and a little falling occasionally, but the child is coming along fairly well now.

Dr. PRICE. In administration as well as in science I think we have to learn by trying things that do not work as well as by trying things that do.

If I may go on to my concluding remarks, I think science is so pervasive a part of modern life that I do not think that in general we should try to organize departments of Government according to their use of particular fields of science or technology. It still seems to me that each major department should include the several activities that are useful in accomplishing some broad public purpose, and that science and technology should be thought of as essential, though subordinate, means to its ends.

But basic science, like education, is an all-important kind of social overhead with a powerful influence on our national purposes. It cannot be tied exclusively to any particular social purpose without being limited and distorted in its nature. It deserves a special and central place in our executive organization, for what it does can have powerful effects on nearly everything else in modern life. And it must work by unusual procedures, since it depends for its effectiveness not on what goes on within its own hierarchy, but on what it can do for a multitude of independent institutions.

If that is the purpose of the National Science Foundation, I am inclined, as I think about its future, to be less concerned about the closeness of its relationship to great agencies with technological programs like the Atomic Energy Commission and the National Aeronautics and Space Administration, than about its relationship to the basic research program of the National Institutes of Health, and to the rapidly expanding support which the Office of Education is giving to universities, and to the future program of the proposed National Foundation on the Arts and the Humanities. The other operating departments and agencies must give priority to their own special purposes, as they consider how to make use of the research services of

academic institutions. But these few have a joint concern for the total health of our system of higher education that must link their interests closely in the future. How that link is to be forged I would not try to recommend or to predict today. In the United States, we can devise a great many ways to develop unity of policy when we wish to do so, and an equal variety of ways to guarantee diversity and independence. The creation of a single department is not always the best way to approach an important purpose, though it may be.

At any rate, the most obvious lesson of the 15 years of history that we are reviewing is that it is not always easy to predict the future. That salutary lesson should excuse me if I end on a note of uncertainty. I thank you for the opportunity of meeting with you today.

Mr. DADDARIO. Mr. Chairman, do you have any questions of Dr. Price?

Mr. MILLER. No; I haven't any questions. I want to congratulate and thank Dr. Price, though, for the very fine statement he made. I found myself in substantial agreement with nearly everything he said.

Dr. PRICE. Thank you, Mr. Miller.

Mr. MILLER. Thank you, Doctor, for coming here.

Mr. DADDARIO. Does that include the note of uncertainty with which he ended his remarks?

Mr. MILLER. If we could resolve all those "notes of uncertainty" in the field of science and its relation to government, maybe we wouldn't be here. It wouldn't be such an interesting and an engaging subject. Is that right, Doctor?

Dr. PRICE. I certainly think so.

Mr. DADDARIO. Mr. Vivian?

Mr. VIVIAN. I really wanted to compliment Dr. Price on a matter of, shall we say, English. I thought for a person who comes from an area famous for the Boston Tea Party that the remark "no subsidization without representation" was applicable.

Dr. PRICE. Thank you, sir; but I have to admit that I don't originally come from that area.

Mr. VIVIAN. We will give you temporary credit for it.

Mr. DADDARIO. He comes from one of those areas that Mr. Roush is always talking about.

Mr. VIVIAN. I would like to go on to another matter. I gather it is still true that the foundation is forbidden by law to operate its own laboratories, is that a correct statement?

Dr. PRICE. I believe it is, as I read the legislative record here.

Mr. VIVIAN. Supposing the laboratories were floating laboratories, would that be acceptable or not?

Mr. MILLER. Don't get too technical.

Dr. PRICE. I don't really know what that term means.

Mr. VIVIAN. In that case I won't refer to any Mohole ships or anything similar. I come back for a moment because of the remarks made about Mohole, oceanography and weather modification—these all to some extent fit under a label called environmental science. There was some interest or some action in this direction to create a haven for a large number of projects which are now split into thoroughly divided authorities. Have you any comments on the wisdom or lack thereof in establishing such an organization within Government?

Dr. PRICE. It seems to me that among the many proposals which carried the label of "Department of Science," and they were so varied that it hardly makes sense to talk about them without being specific, the one which Lloyd Berkner first suggested, which was really an environmental science department, seemed to me to make the most sense. The recent reorganization plan that was submitted to create within the Department of Commerce, an Environmental Science Service Administration, seems to me to be a very sensible step in that direction. If one were to ask the question whether, now that that is set up in the Department of Commerce, we should proceed further to strengthen it and the Department of Commerce as the haven for environmental science generally, then I think you raise two kinds of questions. I don't think I have any specific answer to them, but I think it helps to define the questions. First, in any given instance, would it be better to push this field of science as a basic field, which might suggest that it be kept in the Science Foundation, or as an applied science, which might suggest the Department of Commerce? Second, if it were clearly in the applied field, are we willing to back Commerce all out here at the expense of Interior and Agriculture, because their purposes, too, have to be taken into account if you get to talking about environmental sciences in a broad way?

I don't think these questions are easily answered, and without really digging into detail on any particular proposal I don't think it makes very much sense for me to try to suggest a precise formula.

Mr. VIVIAN. You have no strong recommendation with regard to that particular proposal?

Dr. PRICE. I certainly do not.

Mr. VIVIAN. You made a comment against a Department of Science, and you would not construe that as prohibiting this particular proposal?

Dr. PRICE. Not a bit. I don't think that proposal calls for what is usually considered a Department of Science. I would assume that it would not include the Science Foundation. I assume it would not include Atomic Energy or the Space Agency or the military research programs or most of the Agricultural research programs. The question whether you would want to put together those bureaus and agencies now scattered among many departments which deal with man's environment is a rather intriguing one. I think there is a good bit to be said for it. The disadvantage is that you would tend to pull them out from their close relationship with operating programs and operating purposes. You have to weigh that against the potential advantage of linking them with other scientific programs under a head who is interested in science as such. I don't think there is a conclusive answer on that.

Mr. MILLER. Doctor, isn't it true, though, that some of these agencies find themselves in certain departments of Government for historical reasons that have long ceased to be valid? Let us take the Coast Guard. It has a great academy and it has ships stationed in the ocean continuously, its icebreakers and ice patrol, where great work could be done in the field of oceanography.

The Coast Guard finds itself in the Department of Treasury which has no work related to this merely because once upon a time it was a police organization. Its job was to keep smugglers off the coast from

coming in during the fog with small boats and bringing contraband goods to shore; and later it was used to police prohibition. But it has no present interest in the Treasury, and the Treasury has no present interest in it.

Dr. PRICE. As a former Coast Guard lieutenant, I don't know if I should comment on this. I realize there is a great deal of truth in what you have said about the Coast Guard. It was in the Treasury as Public Health was once in the Treasury. I think if one were to consider its proper place in Government today you could have quite an argument about where it best belongs. I would think Commerce with its responsibility for the regulation and the safety of commerce, in view of the Coast Guard's merchant marine safety functions, which after all used to be in the Commerce Department, would be a claimant. The close relationship of the Environmental Science Agency would add some powerful arguments in that direction. On the other hand, as I remember working on the waterfronts during the Second World War, there were still fairly close relationships with the Customs Bureau. How strong they are today, I don't know.

Mr. MILLER. I think this is very true, but I think we have lagged in some of these things. It wasn't up until about 8 years ago that we cut the umbilical cord of the Coast and Geodetic Survey. Until that time, it could not operate beyond the continental limits of the United States unless by contract with the Navy.

Dr. PRICE. I would think that the closest relationships of the Coast Guard would seem to be with the agency of the Government that has the major responsibility for transportation and a secondary responsibility for environmental science.

Mr. MILLER. I think that is very true. Personally, I think it belongs in the Commerce Department. I tried to put it there once, but not successfully.

Dr. PRICE. I once had a hand in such a recommendation, too, but equally unsuccessfully.

Mr. VIVIAN. I would like to go on, if you don't mind, with the remark you make about the relationship between programs of the National Science Foundation and particularly the Office of Education, the National Institutes of Health and the new Foundation of Arts. I would say the relationship with NIH is not necessarily a very troublesome one at the moment, but I can conceive the Office of Education being a very difficult one as the years go by and as that Office obtains more and more funds. Do you have any remarks to make on that subject?

Dr. PRICE. Yes, I think this is a relationship that could be troublesome and could be highly constructive and highly important. Perhaps I am too much influenced by the fact that I am now in a university and I tend to see the thing a bit from a university perspective. But to the extent that the Office of Education becomes concerned with higher education—and up until recently it was not very much concerned—I think it really ought to be deeply involved in the programs which the Science Foundation got into. It is impossible to separate research and education in practice, in actual operation, particularly at the graduate level. There is a lot of talk about whether we are supporting too much research and not enough education. At the level of graduate instruction I think any effort to separate the two is very

artificial and leads to a great many difficulties. Since the Federal Government decided to go into the support of research but didn't want to get involved in educational support of a general nature, it led to some fairly artificial distinctions, so that the Science Foundation began to do things that the Office of Education—if it had been somewhat more generously financed—might have gotten to first.

If I were looking, say, a half century ahead, and I emphasize that to make it clear that what I am saying is in no sense an immediate recommendation, if I were looking a half century ahead, I would find it very hard not to think about a department which would be concerned with the overall health of our system of education, including research.

It need not be a tightly organized department on a hierarchical basis. It could be a very loose confederation of agencies. I would find it easy to imagine that it would include much of what is now in the Office of Education and the basic research programs of NIH and the Science Foundation, and any new foundation in the humanities and arts field, and then maybe other basic research outfits like the Smithsonian. But I don't think the time is ripe for that yet. I say that only to suggest that I think these are the developing new fields of related interest that have to be watched very closely with respect to the coordination of Federal policies in the near future.

Mr. Vivian. Now, the National Science Foundation has been doing a great deal of work in the training of science teachers. The National Institutes of Health has a somewhat similar activity in the health sciences. The NIH people come under HEW, but the National Science Foundation which also performs an educational function does not. Therefore, if one looks at this objectively, you discover that there should be some relationship to NSF and the Office of Education under Dr. Kappel. On the other hand, to consider this is hearsay to some extent to those currently engaged in these departments; therefore, I recognize even making the remark may not be appreciated.

Dr. Price. I feel much the way you do. I do think that the basic research programs of the National Institutes of Health, while it undoubtedly contributes to the public health function in the same way that the physics program of the Science Foundation may contribute to the atomic energy or military purposes, is really the great supporter in the world of life sciences, basic life sciences. If you take the long-term view, so as to exclude any concern with departmental reactions and interests, it is very hard to keep such basic research support apart from general educational support. I think we have been providing by the backdoor method of research grants a great deal of general educational support, and we probably would do better in the long run to face up to the question and say we are going to support higher education as such. Now, this is not to say that I would like to see us get very far away from the project grant as the fundamental way of dong business in this field. I would hate to see it cut down to less than half of the Foundation grants to universities because it is a system which makes it possible to make grants without raising the specter of political control of higher education. But there is no question that if you go on only with the project grants, just as if you go on with the directly awarded fellowships to individuals, you are going

to continue to build up particular fields of science at the expense of other parts of education.

Similarly, if we are going to be concerned about the institutions which are now not among the small number of leaders, I think the way to do it is very frankly to face the problem that we want to support and build up some centers in regions and areas which don't have first-rate institutions now, and do it by giving grants for that explicit purpose. I think to impose artificial quotas on project grants or individual fellowship grants which are supposed to be made on standards of pure merit causes trouble and debases your standards. I would much rather see the problems faced frankly, and general educational support and fellowship grants given to the universities and colleges concerned if that is the purpose to be accomplished. Private foundations were equally leery a dozen years or so ago of this business of direct general educational support because it requires such a troublesome kind of decision. It in effect means that you must say we are giving to university A and not to university B because we think university A is better than university B, and this is as difficult a decision to make politically for private foundations are for public agencies. But I don't think there is any way to get out of this if you are really going to try to force a geographic distribution of quality in this business.

Mr. DADDARIO. By which I take it, you mean we should?

Dr. PRICE. If I may be personal, when I was with the Ford Foundation I was very strongly in favor of balancing our project grants which tended to go to the blue ribbon institutions with deliberate general purpose educational grants to selected parts of the country—including the one from which I came, which probably had something to do with my point of view—just for the purpose of achieving a better regional distribution. That action was not taken by the Ford Foundation until well after I left it, which probably shows I was ineffective as an adviser. But it was taken, and I think it was a wise decision, and I hope the Federal Government will face up to this some day. But it ought not to fail to recognize that this will be a very difficult job and it will involve real political troubles. Everyone is for it in general, or at least the majority of the people may be for it in general. But discriminating decisions have to be made and this isn't easy. And if you are going to do it you cannot simply do it by giving every accredited institution an equal amount of money. This would really be just a waste of resources.

Mr. DADDARIO. Mr. Yeager, do you have any questions?

Mr. YEAGER. Yes.

You would recommend, then, that the percentage of this NSF budget might be revised somewhat along the lines of taking more advantage of the institutional grants, possibly at the expense of the project grants?

Dr. PRICE. If it is necessary; yes. It seems to me they have been moving quite sensibly, slowly, and gradually in this direction, still tying the institutional grants, as I understand it, mainly to some percentage of previous project grants.

This has the great advantage of not departing from the criterion of competitive merit in some sense. I am not sure when the time will come to depart from that and frankly make institutional grants not

in relation to protect grants in any sense. But I think it is a decision that has to come sometime.

Mr. YEAGER. I have one other question. Do you see any difficulty in the situation where some of the members of the National Science Board are also members of the National Academy of Sciences, which makes recommendations for NSF functions, the President's Science Advisory Committee, or the Office of Science and Technology? Is there a situation in which we have the prosecutor, judge, and jury all bound into one? Is this a difficulty, and if so, is there any way of avoiding it?

Dr. PRICE. If I may take your question and try to break it into two parts, I think there are two questions; one, the question of genuine conflict of interest on specific grants. I take it this is not what you are mainly concerned with. I have not been on the inside of this process. From what my friends tell me, I am inclined to think that they rather lean over backward to avoid this kind of favoritism.

If you get to the second more general question, do we get an inadequate spread of general policy opinions as long as there is this much interlocking of personnel, I think we probably do not, but I don't know what to do about it, and I think this is inherent in human nature and human institutions. If the National Academy of Science is expected to include the blue ribbon scientists in this country, we would not want to pass a law that the Science Board should not include any first-rate scientists. I would think that we would wish to rely in matters like this on the fact that they are both pretty big institutions. The Science Board is not made up exclusively of members of the Academy. It has a very good geographic distribution.

And besides, the whole structure that we are actually talking about is so pluralistic anyhow that I should think it would be very easy for this committee and private scholars in the field to get on the inside and know what the issues are and what the divisions of opinion are, and whether there is in fact any sort of clique operating here. It is not my impression that this is a serious problem. It is my impression that it is a chronic and pervasive problem in society, but I don't see it as being serious in any peculiar sense in this field, and perhaps rather less in this field than in most.

Mr. YEAGER. Thank you.

Mr. DADDARIO. We would like to send some additional questions to you. We will try to keep them to a minimum.[1]

Dr. PRICE. I will be delighted to try to answer them for you.

Mr. DADDARIO. I want to thank you for your testimony and for your answers to the questions. They were very helpful to this committee and to its objectives.

This committee will adjourn to the same place tomorrow morning at 10 o'clock.

(Whereupon, at 12:15 p.m., the committee was adjourned to reconvene Thursday, July 8, 1965, at 10 a.m.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

THURSDAY, JULY 8, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. The meeting will come to order.

Our first witness this morning is Dr. Alvin M. Weinberg, who is the Director of the Oak Ridge National Laboratory. Dr. Weinberg previously appeared before this committee with the panel that presented the National Academy of Science's report on "Basic Research and National Goals." We are very happy to have you with us this morning, Dr. Weinberg.

STATEMENT OF DR. ALVIN M. WEINBERG, DIRECTOR, OAK RIDGE NATIONAL LABORATORY

Dr. Weinberg. It is a very great pleasure to be here again, Congressman Daddario.

I have a statement which I will read for the record, if you would prefer it that way. This statement is called the "Future Role of the National Science Foundation."

Most of my views on the role of the National Science Foundation have already appeared in my contribution to the National Academy report on "Basic Research and National Goals." I shall summarize the argument I presented there favoring a greatly expanded National Science Foundation, especially as a source of support of university-based physical science.

The argument is simple:

Table I.—*Federal obligations for conduct of basic research*

[In millions of dollars]

Department or agency	1962	1963	1964	Estimated 1965	Estimated 1965
NSF	105.5	144	170	212	290
HEW	190	236	265	298	330
DOD	178	198	260	293	324
AEC	192	219	238	260	286
Interior	30	29	33	37	41
Commerce	16	21	22	24	27
Agriculture	50	56	62	82	85
Other	8	9	1.5	1.8	1.4
NASA	316	447	756	910	888
Total	1,085	1,359	1,808	2,118	2,272
Percent supported by NSF	9.2	10.6	9.4	10.0	12.7

I obtained table I from the report "The National Science Foundation—General Review of Its First 15 Years." Incidentally, I might say I enjoyed reading that report very much, and I want to congratulate Dr. Wenk and the other members of the Legislative Reference Service of the Library of Congress for putting together a really excellent document. I thought it was a major contribution to the literature.

Mr. DADDARIO. I am pleased to hear you say that, Dr. Weinberg. It indicates that it has been read within the scientific community. We have received similar reports from other places, and had hoped that this report might be helpful both to the members of the subcommittee and to the scientific community.

I am pleased to hear from you that it has been helpful.

Dr. WEINBERG. I hope you, in turn, pass this view on to Dr. Wenk. I think he and his staff have done an excellent job.

Mr. DADDARIO. I think a few members of his staff are in the room right now.

Dr. WEINBERG. This table summarizes the funds spent since 1962 for basic research by Government agencies. According to the table, the National Science Foundation—the one Government agency whose mission is explicitly to foster basic research—has consistently supported only about 10 percent of all the basic research funded by the Federal Government. This means that each of the other Government agencies, insofar as it has supported basic research in the same spirit as does the National Science Foundation, has operated a sort of informal "NSF." We have not one NSF, but nine "NSF's." Of these, four (HEW, DOD, AEC, NASA) are in fact larger than "the" NSF.

The rationale behind support of basic research by the mission-oriented agencies is, I believe, perfectly plausible. Each of these agencies uses science and technology to accomplish its mission, the mission itself being specified by Congress. Each agency therefore has a responsibility to the basic science that underlies the technologies necessary for achievement of the agency's politically defined mission. For example, DOD, as the agency responsible for defense of our country, supports massive research at universities in, say, solid state physics or basic metallurgy because so many of DOD's mission require sophisticated technical applications of knowledge from these fields; or Health, Education, and Welfare, with broad responsibilities for the health of our Nation, supports basic research in the biomedical sciences.

The mission-oriented agencies have tended to look upon their support of basic research in much the same way as the director of an applied laboratory looks upon basic research in his institution. His laboratory's aim is, say, to devise methods of desalting the sea or of controlling fusion. These are, in fact, jobs that we are heavily engaged in at the Oak Ridge National Laboratory.

In order to achieve these ends, the laboratory director must devote significant effort to basic research in fields that he considers to be broadly relevant. The judgment of relevance depends largely upon the taste and style of the laboratory management, just as the judgment of relevance by Government agencies as a whole depends on the sophistication and experience of the agency managers. The basic research in an applied laboratory (or in a mission-oriented agency) is a necessary expense incurred by the laboratory (or agency) to maintain the sophisticated scientific environment necessary for getting on with

the applied work; or in the expectation that very new and unexpected findings of relevance will crop up; or to elucidate troublesome points that arise in the course of the applied work.

I might give a beautiful example of an incident in this connection. The members of the Committee on Science and Astronautics are aware that in the periodic chart there are the so-called rare gases—helium, argon, xenon, krypton—which are supposed to be completely inert. They are not supposed to undergo any chemical change at all. This was a fundamental fact of chemistry that had been known for, say 100 years. It happened that Bartlett at the University of British Columbia a couple of years ago noticed that xenon, in certain respects resembled an ionized state of oxygen.

Therefore, he began to question whether the inert gases really are so inert. He tried to make compounds of xenon that were analogous to compounds of oxygen, and, sure enough, he discovered that xenon wasn't inert. So crumbled a whole edifice of chemistry that had been in all the chemistry books for many years. This discovery was then picked up by our sister institution, the Argonne National Laboratory, and a whole chemistry of xenon compounds was developed.

I mention this because at our laboratory we had for many years been working on a very special kind of nuclear reactor, the so-called fluoride reactor, in which the uranium is present in the form of a molten fluoride. We noticed that when the uranium underwent fission, among the fission products there were xenon and krypton. Further, for about a year, under circumstances where fluorine was suspected to be present for other reasons, we always found that the xenon was missing. The krypton was present but the xenon was missing, and we couldn't understand where it went, since all the chemistry texts claimed that xenon cannot form any compound.

Therefore, obviously, we weren't doing our analyses very well. One engineer at our laboratory maintained that maybe the chemistry books were wrong, that xenon does form a chemical compound. Our chemists paid little attention to him; the chemists said engineers don't really know very much about chemistry. About 6 months later we learned about Bartlett's discoveries which explained the discrepancy. Bartlett's work was basic research in its purest form, but it elucidated a very troublesome point that we had encountered in the course of our applied work.

This is an example of how discoveries in basic research make a real difference in getting along with the applied business of the laboratories of our country.

To get back to the main story, over the past decade, most of the major agencies supporting basic research as a necessary overhead for the accomplishment of their applied missions have acquired a tolerant attitude toward the question as to what is relevant and what isn't relevant. This attitude is justified by the well-known unpredictability of basic research, as evidenced by the anecdote about xenon.

Of course, there are many other such examples that justify the enlightened attitude that our agencies have toward basic research.

Because the four major mission-oriented agencies, AEC, HEW, DOD, and NASA, have been willing to act as national science foundations in their support of basic research, particularly at universities, basic research in the universities has flourished.

But I believe most of the mission-oriented agencies face all but insoluble problems in their continued support of basic research, particularly at the universities. For if basic research by these agencies is viewed as a means to accomplish their politically defined, nonscientific goals, then the level at which basic research is supported by the agency ought to bear some relation to the total budget allocated to it by Congress to accomplish its mission. This is not to say that even if the budget of the agency remains stationary the agency should not allocate a larger fraction to basic research. But the degree to which any agency can or should play this game, diverting more and more money to basic research, is, I believe rightly, limited; I don't, for example, believe that our own laboratory, established to achieve applied missions, ought to become a basic laboratory simply because Congress decides that its applied missions are no longer important enough to warrant continued support. In the same way, I think an agency established to accomplish a politically defined goal should not become merely a supporter of basic research because its politically defined goal is no longer deemed to be very important. On the average, the basic research budget of every mission-oriented agency must be a reflection of the budget of the entire agency.

But this is precisely why the role of NSF seems to me to be so important in the coming years. Of the four mission-oriented agencies, HEW, AEC, DOD, and NASA, that have supported basic research most heavily in this country, three—AEC, DOD, and NASA—are devoted to missions whose importance does not seem to me at least to warrant increases in overall budget, or very significant increases in the overall budget. In fact, spending for defense, atomic energy, and space already have leveled off. Except for the great issue of civil defense (which in any case has few implications for basic science), I cannot visualize public problems lying within the province of these three agencies that would justify much expansion of their budgets. Insofar as these three agencies support a considerable fraction of our basic research, particularly in the physical and engineering sciences, it seems obvious to me that these agencies will be unable to continue to provide the growing support these sciences will demand.

The Department of Health, Education, and Welfare, and the biological sciences generally, I view in a different light. As I look at our deployment of scientific resources or, for that matter, our governmental resources, I am convinced that more should be allocated to the biomedical sciences. The elementary human suffering that more knowledge in biomedical sciences will surely help relieve is so obvious, and is so important to each of us, that I would urge all possible haste in pushing at the frontier of biomedical knowledge.

I think this view is shared by Congress and by our people. Thus, even though this year's budget for NIH has not increased as fast as I think it should, I rather confidently look forward to NIH becoming a $3 billion agency by the early 1970's, simply because the problems it addresses itself to are so important, and because the time is so right for making tremendous progress in the biomedical sciences.

Because of my conviction that NIH will expand rapidly, I have little concern about support for basic biomedical science. NIH has been tolerant and sophisticated in its support of basic biomedical sciences in the past, and I believe it will continue to be tolerant and

knowledgeable in the future. I visualize NIH greatly expanding its role as a National Science Foundation for the basic biological sciences; I believe this role is justified and strongly in the national interest. In fact, in answer to the second question put to our NAS committee by the Daddario subcommittee—and I paraphrase the question—"How should we deploy our scientific resources?" I answered, "Make the coming age the age of biology." I see no reason to change my mind on this score.

Though the biomedical sciences ought to be well taken care of over the next decade, the physical sciences, being the handmaidens of agencies that are unlikely to expand very much, can hardly expand unless some positive action encouraging such expansion is made by Congress. But first I ask, "Why should the basic physical sciences be encouraged to expand?"

In answering this question, I point out that science, by its very nature, tends to expand and to proliferate. Every important discovery, at the same time it resolves one pressing question in science, raises many other questions; more than that, it may provide a technique for examining questions which were intractable or had not been thought of before the discovery was made.

Thus, insofar as our country is committed to support of basic science, it is committed to an expanding kind of activity, simply because the internal logic of basic science forces it to expand. Science is, indeed, an endless frontier.

This tendency toward expansion is accentuated by the growing demands of our educational system. As more of our population goes to college, a larger number of students will elect to study the sciences. Insofar as our Nation is committed to providing its citizens as much education as we can afford, the growing college enrollment in physical sciences will place heavier demands on our scientific resources.

Present studies by National Academy committees of physicists and of chemists suggest that this pressure for expansion of our educational institutions will require about a 19-percent increase in university science each year.

I believe this gradual "scientizing" of our society will have important implications for many crucial public problems that we now see emerging. Most of these problems, like the despoiling of the environment, or urban transportation, or urban sprawl, do not obviously fall directly in the physical sciences. Yet the physical sciences will surely contribute heavily to our attacks on them—partly directly, as in the development of an effective catalyst that eliminates noxious fumes from our auto exhausts; or indirectly, as people well grounded in the discipline of the exact physical sciences transfer into the more complex, more difficult, social sciences. How such transfer might work has been demonstrated to me at the Oak Ridge National Laboratory where we have launched a civil defense project to examine the entire question of civil defense. The leader of the project, Eugene P. Wigner, is a Nobel Laureate in Physics; but he has made a partial transition to the social sciences. I am convinced that the habit of thought and background he acquired as a physicist has equipped him for a sophisticated attack on the problem of civil defense.

If we agree that the basic physical sciences ought to continue to expand, though not as fast as the biological sciences where will the money come from?

I see three major sources: First, many of the physical sciences, notably chemistry, are germane to the biomedical sciences. I therefore believe it to be entirely proper that these branches of physical science be recognized as handmaidens of the biomedical sciences, and that the burden for some of their support be assumed by NIH. To some extent this is already being done: NIH is the single largest Government supporter of basic chemistry in the universities. This is a statistic that often comes as quite a surprise to those who study this matter.

What I argue for is an expansion of this commitment to the physical sciences as the budget for NIH itself expands.

Second, as we mobilize around the new public problems I identified earlier, like the problem of urban transportation and air pollution and so on, and assign them to Government agencies, or as new agencies are established to deal with them, these new agencies ought to give some support to the basic physical sciences. For example, one of the newer large-scale missions of Government, the achievement of economical means to desalt the sea, has already served as a source of support for certain kinds of basic research in solution chemistry and thermodynamics. However, since most of these newly emerging problems seem to me to lie in the social sciences, I do not expect agencies or offices charged with these missions to accept much responsibility for the health of the physical sciences, even though the latter are indirectly relevant to what they do.

The main source of support for our expanding basic scientific enterprise, particularly in the physical sciences, must therefore, I believe, be the National Science Foundation. The budget of the NSF for 1965 was about $400 million, an increase of some 15 percent over 1964. I would strongly urge that this trend be maintained and even accelerated so that by, say, 1970 NSF's budget would exceed $1 billion per year. As I see it, by this time NSF and NIH would be the largest basic scientific agencies: NIH being concerned primarily, though not exclusively, with the biological sciences, NSF primarily, though not exclusively, with the physical sciences, especially in the universities, and with those aspects of science that are not properly taken care of by one of the mission-oriented agencies.

To my mind this would imply a major simplification in the way we fund science. At present, as I pointed out at the beginning of my testimony, most of our basic science is supported by our mission-oriented agencies as a justified overhead expense for the accomplishment of their missions. But these missions in general are not likely to grow as fast as the pressure to expand basic physical science.

Thus, we shall soon be unable to support our expanding basic physical science merely as assessments on relevant missions. Instead, we must decide whether basic science per se, only indirectly relevant to specific applied missions, or as an adjunct of education, should continue to receive more support from Government.

This debate is perfectly justified, and should be encouraged, not submerged. The proper focus for this debate is the National Science Foundation. As the Foundation becomes the largest supporter of basic research per se, particularly in the physical sciences, I would anticipate that the debate in Congress concerned with NSF will be the main annual forum at which the Nation decides how important we think basic research is in our scheme of things.

The debate will inevitably involve the whole question of the relation between Government and higher education. The stabilization of the budgets of AEC, DOD, and NASA hits university-based science more heavily than it does science in the Government laboratories. The size of a Government laboratory, and its budget, is determined by the needs of the agency it serves. If the agency's overall mission is not expanding, the Government laboratory supporting that mission will not expand. This does not mean that there are no pressures to expand within a Government laboratory.

There certainly will be such pressures. But these pressures are, in principle, under the control of the Congress, and are no different than the expansionist pressures of any other part of Government.

The pressures for expansion of science within the universities, on the other hand, come from the inexorable rise in population and from the "scientizing" of our culture. This pressure to expand will remain on the universities unless Congress decides, year after year, not to respond, in which case we would gradually expect a smaller and smaller fraction of our population to turn to science. This would be unfortunate.

The expansionist pressure on university science has led, in the past few years, to considerable rivalry between university and Government laboratories. The expanding universities place pressure on the mission-oriented agencies that support them for a greater share of the agencies' limited research budgets. Since a dollar spent by an agency in an in-house or contractor-operated laboratory is unavailable for science in the universities, tensions arise between the university and the Government laboratory. This was brought into the open by the Wooldridge committee, which examined the basic scientific support methods of the NIH. The Wooldridge committee suggested that basic research in the NIH's own laboratories might be cut back and university research expanded.

As a representative of a quasi-governmental laboratory, I can only view a weakening of these institutions in favor of the universities as undesirable. The Government laboratories, being mission oriented, are directly responsive to the needs of the agencies that support them. Basic research in these institutions is done because it enables the laboratories to get on with their applied missions. Take away the basic research and you will soon lose your capacity to do the applied work efficiently.

I strongly sympathize with the plight of the universities, and I strongly believe it to be in the national interest to support more university-based research. Because not much of the expansion can, as I see it, come from DOD, NASA, or AEC (since I do not approve of diverting support from the governmental laboratories to the universities), I believe university science shall have to look, much more than it has in the past, to the HEW–NIH complex—for biology—and to the NSF for the remaining sciences. Thus, in the future NSF will be even more intimately involved with the universities than it has been in the past.

Eventually, I would visualize much more than half of the university physical science as being supported by NSF. Though there are some scientific voices which suggest that provision of so large a fraction of the university science budget by a single agency would make

the entire scientific enterprise too vulnerable to the whims of a possibly unsympathetic Congress or administrator, I am much more optimistic about the future.

Our country has reached a degree of scientific sophistication where science for its own sake has become a real goal of our society. Congress has taken a generally understanding and sympathetic attitude toward this goal.

I have no doubt that, in the years to come, the debate on NSF and its funding will bring out the national attitude toward basic research, and that this attitude will be a congenial one. Such debate is the essence of our democratic process. I am confident that, over the long pull, the NSF and the universities it supports will receive a share of our resources commensurate with the great contribution they make to our society.

Mr. DADDARIO. Dr. Weinberg, you view the research departments in some of these other agencies as being National Science Foundations in themselves. As you have put that into perspective you have indicated that DOD and NASA will have funding problems when their mission objectives level off. If the amount of basic research being done throughout the Government is not adjusted during the period of time when funding is at a fairly high level. You are concerned that the overall percentage of activity which is being accomplished in the Government will come down. You recommend adjusting the amount of basic research now while conditions are favorable to the overall effort, is that correct?

Dr. WEINBERG. I am not sure I entirely understand. Are you referring to adjusting the fraction of, say, the NASA and the DOD budgets that go to basic research at this time?

Mr. DADDARIO. Yes.

Dr. WEINBERG. I think that one cannot set an absolute value on this number. I think the trend will be toward increasing this fraction as more and more of the missions of these agencies are viewed as having been accomplished. The fraction of an agency budget devoted to basic research is necessarily limited; insofar as possible it ought to be settled in advance. This would enable us to know where else we have to look to accommodate, the pressure for expansion of basic research in the universities.

Mr. DADDARIO. The trend is toward NSF and NIH being the largest basic scientific agencies. As I understand it, you think it should go in this direction?

Dr. WEINBERG. I think it is inevitable. I think it should go this way. To paraphrase what I said, I don't really see a problem with respect to the biological sciences. Because the NIH has done such a fine job and because the problems in biology are so important, the biological sciences won't really have to worry over the next decade. Support for basic research in the biological sciences in the universities won't really have to worry very much. But in the physical sciences I just don't quite see how one can do the same thing because the agencies that have been largely responsible for basic research in the physical sciences happen to be those agencies whose missions are not going to really expand, I think Congress has rather taken this view as shown by its action with respect to the DOD or the AEC or the NASA budget. The AEC budget, for example, is a little

less this year than it was the previous year. So if there is, nevertheless, real reason for expanding basic research in the physical sciences—reasons that are not directly connected with the missions of the agencies—I see no other home for this expansion except within the National Science Foundation. We will then get out on the table the question of how important we really think basic research for its own sake is, rather than always tucking such basic research under the umbrella of mission-oriented agencies.

We have generally tucked a great deal of basic research under the umbrella of the mission-oriented agencies, which is fine. What I am saying is the game cannot be played to advantage very much longer. We are at a stage in our scientific Government policy where we have to look squarely at the question of whether we are going to allow basic research in these other sciences to expand, and this comes back to what you are going to do about the National Science Foundation. I therefore, am very grateful to you and your committee for holding these hearings, because I think this question of what is going to happen to the National Science Foundation is the most important single question connected with the future of basic science in the United States.

Mr. DADDARIO. This discussion will become a very important one and I think you have added a great deal to it this morning. When you state that the mission oriented agencies have acquired a tolerant attitude toward the question of what is relevant or what isn't relevant, have you seen tendencies for this attitude to change as the budget limitations become more stringent on the mission oriented agencies and as they tend to look to another agency to do the basic research they cannot afford? In other words, at this stage of the game do they look toward NSF and NIH to do basic research?

Dr. WEINBERG. I think that is correct. I think there is no doubt about that.

Mr. DADDARIO. How might we bring more order into this situation and emphasize the importance of proper transfers at this time? Does the 15-percent increase toward the $1 billion or so in 1970 mentioned on page 9 provide sufficient funds to take care of this adjustment?

Dr. WEINBERG. I guess I shouldn't be held too strongly to the figure of $1 billion. I say "exceed $1 billion by 1970." One billion just seems like such a big number to me; by saying that NSF was a $1 billion agency, I was giving voice to my strong belief that NSF has to become a very major element in the Government; it may be by that time it should be a billion and a half or possibly even more. I think the 15-percent rate of increase for NSF is too low for the next half dozen years, and how much above $1 billion it should go I really can't say. What I am trying to do is to urge Congress to focus on this question because I see it as the central question.

With respect to this other matter of how to encourage the mission-oriented agencies to retain a tolerant attitude toward basic research, I don't really have any very clear answer. I think the mission-oriented agencies, as long as they really have an essential sense of purpose, will have to make sure that they do whatever is necessary to get on with their essential purpose. The thing that I would dislike to see happen would be that somehow the importance of what an agency is doing is deemed to be much less than it was, say, when the agency

was founded; and since an agency always has an innate desire and imperative to survive, it will, under those circumstances, divert more and more of its money to basic research simply as a means to survive. That I would be against. But I think there is some possibility that something like that might happen with some of the agencies.

Mr. DADDARIO. I don't intend to indicate that either I or this committee is in favor of their having the most tolerant attitude. It seems to me that they ought to do what is necessary. Then there should be an adjustment of the NSF's role in relationship to the other agencies such as NIH.

Mr. Brown?

Mr. BROWN. Dr. Weinberg, I consider your paper to be extremely stimulating and aiding in the discussion of these problems which we are reviewing here. In a general way, the figures in your table on page 1 and the other data that is available, indicate that currently a very substantial majority of the funds being spent on basic research are in the physical sciences. Do you think there is any basic criteria which should govern relative support of the physical and the biological sciences?

Dr. WEINBERG. Mr. Brown, you probably know that although I am a physicist I have been sort of ruled out of the physics community because of my statements about spending as much as we do on some of the more arcane branches of the physical sciences. My deep conviction is—when we ask where we are going to put our money in basic research, if we have to make a choice—that we are not spending enough in the biological sciences.

Mr. BROWN. You indicate that in your paper.

Dr. WEINBERG. At present the physical sciences are favored by a factor of 3 to 1 or 4 to 1. I think that is wrong; it should be much closer to 1 to 1.

Mr. BROWN. That makes you a traitor to the physical scientists?

Dr. WEINBERG. I used to be a biological scientist, but that is not why I think this. The sort of thing I'm talking about is so evident. We have in our laboratories some extremely worthwhile work, implicating viruses in leukemia. Now, the thing seems to be somehow very near at hand. At the NIH, for example, they have done experiments in which they have actually immunized mice against leukemia by injecting a certain virus extract. One can't help but say that it's worth just an awful lot of money to really get this thing solved, especially when he turns around and sees examples, and we have examples at our laboratory, of people in the prime of life who are struck down by leukemia. How much would it be worth to the world to have a real cure or control for leukemia? Well, I don't know. To one who is afflicted by leukemia prematurely, it is worth all the money he has. It is on this account I say that somehow we have allowed allocation to the various sciences to be warped, and we don't, it seems to me, really keep in mind the idea that our ultimate purpose as human beings is to lead the best kind of life that we can. It is on this account that if you ask me where we should put more money, I would say put it in the biological sciences.

Mr. BROWN. You are not suggesting an actual ratio but an increase in emphasis on the biological sciences?

Dr. WEINBERG. Yes.

Mr. BROWN. Let me suggest a line of thinking which might go contrary to the line of thinking that you have advanced here. The mission-oriented agencies by virtue of their missions are not going to be able to expand their contribution to basic science. Therefore, we need an increasing role for the National Science Foundation. Has it not been true in the history of recent years that as basic science has expanded new missions have been created and new mission agencies have been created? Isn't NASA itself, for example, an outgrowth of developments in basic science? And is it, therefore, not possible—to take an example, as we make breakthroughs in say population control that there would be established an agency, national or international, devoted to population control which as a mission-oriented agency would stimulate additional research in the biological sciences?

Dr. WEINBERG. Yes; I quite agree. As a matter of fact, in my paper I do speak precisely to that point, that as we see these new public problems developing we will presumably assign them either to new agencies or to new offices, and these new agencies and new offices will themselves serve as sources of support for research which is basic but which is relevant to these missions. My only point is as I visualize the situation—heaven knows my crystal ball is as cloudy as the next fellow's—I do not see these problems arising particularly in the physical sciences; rather they all seem to have a systems character or a social science character. Therefore, I don't see how to accommodate the innate tendency for the physical sciences to expand unless the National Science Foundation is expanded.

Mr. BROWN. That leads me to another point which I have brought up with some of the previous witnesses. On page 11, you have made the statement that you believe university science will have to look much more than it has in the past to HEW and NIH for biology and to NSF for the remaining science, and eventually you visualize much more than half of university physical science research being supported by the NSF. You have just made the statement that you see the problem areas developing as being those related to systems approach to social problems. Nowhere in here do we have a discussion of the social sciences. I get the feeling that you as well as many of the other scientists do not look upon these as sciences.

Dr. WEINBERG. No, I think that doesn't express my view quite accurately. I have had a fair amount of contact with social scientists in the past year because for part of our civil defense program at the Oak Ridge Laboratory we actually have social scientists at our Laboratory. I have had many discussions with them on these questions. In fact, yesterday I was reading a paper by a very excellent social scientist, social psychologist and psychiatrist called, "A Manhattan Project for the Social Sciences." I would only say the following: I really believe the problems that the social scientists are trying to address themselves to, if anything, exceed the importance of the problems that biological scientists address themselves to, but I think one has to remember that before one can pour large sums of Government money into any field of science one has to have fruitful points of departure. In the biological sciences I think I see very fruitful points of departure.

In the social sciences, much as I would like, I really don't quite see fruitful points of departure. Therefore, in response to the suggestion by this very able psychiatrist that we have a Manhattan project for the social sciences, I had to tell him that in my opinion it would be fine if we knew where to spend the money, but I don't really see where to spend large sums in the social sciences.

Mr. BROWN. Let's look at the problem of population control, for example. There are many people who say we have wasted all the money that we have spent on foreign aid and a good part of what we have spent on defense because we have done nothing about population control. Now, this isn't strictly a biological problem; it certainly isn't a physical problem. It is basically a social science problem. We can develop the contraceptive devices but how do you convince India with its culture and Africa with its many cultures or South America? I think you can see the importance of this. The problem is not that we don't have a mission, it is that we don't see the mission, and we cannot convince Congress or the scientific community of the mission.

Dr. WEINBERG. I couldn't agree more with you in this particular instance, Mr. Brown. I do think that the population problem of the world is in some sense the problem, and I agree also that the solution to it lies much more in the domain of the social scientists than of the physical scientists.

However, I guess I still would say I don't quite see how by spending let us say $300 million to study the problem of population control one is likely to assure success on the problem. Somehow, with so many of these very complicated systems and social problems, my view is that you have to take an engineering approach, that you have to do what you can with the knowledge that you have, at the same time trying to get as much knowledge as possible but not depending on having all the knowledge necessary to really solve the problem at some specific time.

Mr. BROWN. Would you have said in 1938 that with the expenditure of $200 million we could develop the hydrogen bomb?

Dr. WEINBERG. Indeed not, but I would only make the following rejoinder, and it is to the suggestion to have a Manhattan project of the social sciences. I suggested to my friend, that if one wants a Manhattan project of social sciences, he must show me the discovery of fission or the equivalent to the discovery of fission before I give him the money. As soon as he has the point of departure, I am willing to give him as much money as possible. Until he has the point of departure, until, so to speak, one has discovered fission, I think the small-scale individual kind of investigation is the sort of thing that is needed.

Mr. BROWN. I think any discovery of fission starts with a few people who understand the phenomena of fission. Einstein was evidently able to see the possibility of a hydrogen bomb when no more than 2 dozen people could see it. There are more than 2 dozen people who see the problem in the social sciences today.

My question is directed to this problem. I think the concept of fission in the social sciences is here. It may be in the population problem, or it may be in any number of other problems, but we don't seem to have that catalytic situation. An Einstein can say to a President, well, here is the potential that will allow us to get some action.

As an example of this, you probably noticed a little flurry in the papers recently about the Defense Department spending $20 million

on social science research, one of the projects being Chile. This maybe should have been funded by some other department, possibly the State Department, or possibly some department completely devoted to social science research such as comparative economics of societies or political science. We don't have such an agency now. The Defense Department can get $20 million to do this because nobody cares about $20 million in a $50 billion budget. This would seem to indicate that perhaps the problem is in the thinking of the policymakers rather than in the lack of a need for basic social science research.

Dr. WEINBERG. I want to make very clear, Mr. Brown, that I agree completely with you on the desirability of using the social sciences and the desirability of making progress in the problems that social scientists address themselves to. I suppose the only respect in which I disagree is that I don't really see how the social scientists at their present state of development, without breakthroughs of the sort that fission implied for nuclear energy, can make use of vastly greater sums.

A Manhattan project for the social sciences now—I just wouldn't understand it. On the other hand, I want to say again I respect social scientists and I would like to see them supported. I think the social scientists themselves are not complaining very much at the moment about support.

Mr. BROWN. It is just the physical scientists such as yourself who are complaining about not getting enough money for biological sciences.

Dr. WEINBERG. I should explain again I have practically been run out of the physical science community.

Mr. BROWN. Thank you.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Doctor, I am interested in your discussion of potential competition between the universities and the in-house laboratories. Is this a serious problem now?

Dr. WEINBERG. It is a little difficult to say whether or not it is a serious problem. I see it developing, and it develops for the obvious reason that both kinds of institutions get their support from the same limited source.

Mr. CONABLE. Our universities are much more dependent upon these grants than they used to be, are they not?

Dr. WEINBERG. Very much more; that is right.

Mr. CONABLE. They are almost in the same position as that of the in-house laboratories. Although they have other strings to their bow, this is an important consideration?

Dr. WEINBERG. That is right. Of course, in the universities there is an inexorable pressure to expand simply because there are more youngsters going to school. Therefore, the universities keep getting bigger and bigger, they have to provide sophisticated scientific education for more and more students, so they always go this way, that is, upward. The colleges have depended, say, on AEC for a good deal of support in basic chemistry, but AEC only has a limited budget. AEC has its own laboratories that are fulfilling missions that are relevant to its business, and just don't have the money to go around.

Mr. CONABLE. Is this competition likely to lead to some serious coordination problems?

Dr. WEINBERG. I view it as being a source of increasing difficulty as the years go by, as the financial pressure on the universities increase. Being the director of one of the national laboratories, perhaps I feel it more sensitively than people who are not in this position.

Mr. CONABLE. From your vantage point is the Science Information Exchange doing a good job?

Dr. WEINBERG. I think that is a very complicated question, Mr. Conable. I haven't really been in science information for nearly 2 years. I think at that time, as our report said, the Office of Science Information Service (OSIS) is doing some things very well, is providing information on what is going on in science throughout the country and through many of the agencies, and is supporting new publication ventures advantageously. The thing that the OSIS is not doing is really serving as an overall science information service as VINETI does in the Soviet Union—as actually an operating service. I think in much the same way as the role of the National Science Foundation as a whole has not developed into coordinating all the science of the Government, so OSIS has not been able to coordinate all the science information services in the Government.

Mr. CONABLE. Is this their fault, or the fault of the agencies not cooperating with them? For instance, does your laboratory cooperate with SIE?

Dr. WEINBERG. With SIE we do, that is Science Information Exchange. We send our summaries of research to them. With the Office of Science Information Service there has been no real opportunity for our laboratory or even for the Atomic Energy Commission to cooperate in the sense that I think you perhaps have in mind. I think the primary reason has been that the National Science Foundation, although when originally established, it was visualized as having a kind of coordinating role for all the science in Government, actually has developed into just another science agency, although a very important science agency, and it was perhaps asking too much for the Office of Science Information Service to assume the overall coordination of science information for all Government agencies. My own belief is that the Committee on Science and Technical Information of the Federal Council for Science and Technology is doing a good job and is taking over some of the functions that were originally envisioned for OSIS.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I would like to paraphrase a remark made yesterday by Chairman Miller of the full committee when he said he thought a speech was very excellent because it reflected his own views very strongly. I must say your own remarks fit into that category. I think they are very pertinent. I envy the Oak Ridge staff for having such an outstanding director.

I would like to back up some of Mr. Brown's remarks on the subject of the social sciences, but I want to refer to motivational sciences for a moment, which is only a part of the social sciences. With the advance of the physical sciences, the biological sciences have been able to move much more rapidly. For example, the improvements of instrumentation aided the biologists enormously. I think with the advance in the computer sciences the possibilities for increase in the knowhow of the motivation sciences are riper than might be suggested.

I perhaps would suggest to my colleague here that this is one of the places where the full force of present technology can be presently put to work, and with enough of a point of departure, to be productive.

I think we are all aware of the number of sufferers, say, from cancer in this Nation. There have been probably as many persons killed in Vietnam. On a microscale the number of traffic fatalities on a Fourth of July weekend exceed the number of Americans killed in Vietnam in 4 years. So the motivational sciences would be a productive area.

To go further, you mentioned "scientizing" our society. That is not so much a dedication of science but a dedication to education generally. It seems to me science in this respect is just one facet of education, and a more modern version of the same. Aren't you really saying we direct ourselves to the idea of a very much advanced education in which everybody becomes familiar with science, rather than being a devotee or practitioner of science?

Dr. WEINBERG. Very definitely.

Mr. VIVIAN. I have been using a phrase, "the image of the age," namely, that science is going to solve most of our problems in the future. I have been pointing out to a number of my audiences that research has pretty well flattened off, the numbers of dollars you can count in the private research sector has flattened off, and I am basing this on statistics collected by the Government, which are never accurate but are at least indicative. The basic and applied areas within the Government itself have also flattened off. As you have commented, DOD, AEC and NASA curves now have a very distinct flat spot on them with no gross evidence of a sizable rise. I think in the Department of Defense the only obvious reasons would be some drastic change in the defensive anti-missile-missile business which could be an enormous influence and would have tremendous policy connotations far beyond any scientific connotations. At the Atomic Energy Commission, my impression is that the new accelerator will influence the budget in the future merely because of operating costs.

I think it is a step which we will eventually have to take. The NASA budget has been leveling off. So if we take the private sector and the public sector, we find that "the image of the age" is coming into conflict with the realities of financing. We are bound to see more people trained in science with this 15-percent-a-year rise, who will have to be financed in science or related activities such as motivational activities or who will simply have to take their knowledge or talent and move into other fields of endeavor. This is a pattern which is emerging and I think your comments have illuminated this very, very well, far better than I have been able to do in the past.

I would like to go into a facet of this which you have mentioned. You suggested that a fraction as large as a half of the support for university science if it came out of NSF would be worrisome to the members of the scientific community. I am very familiar with these worries. I think they are justified but I don't think that a factor of one-half is serious. My own personal thinking is it should be at least one-half through NSF. Do you have any comments on the fraction?

Dr. WEINBERG. I think my sentence——

Mr. VIVIAN. Page 11.

Dr. WEINBERG. Didn't I say rather more than half?

Mr. VIVIAN. Much more than half.

Dr. WEINBERG. And by much more I mean 75 percent or 80 percent. Eventually, as I see the thing developing, I visualize NSF becoming the source of support for the bulk of a large segment of university science. I think you put it well, Mr. Vivian, when you state that some university scientists view this with considerable trepidation because they believe there is strength in multiple sources of support. In some sense there is strength in this, but, as I look at it, if we think that science is really important, we should be willing to argue this each year and say that science is very important and we are going to allocate a big piece of our resources to the support of Government science. Such debate would be best focused if a large fraction of our support came from a single science-oriented agency, that is, NSF.

Mr. VIVIAN. I think a a good percentage would be between 60 to 70 percent. Because NSF deals so heavily with grants rather than contracts to the universities themselves, I feel that such a large percentage is not as adverse as it would seem. I don't think it should be larger than 60 to 70 percent.

Dr. WEINBERG. I think I would agree, although I disagree with some of the implications of the statement that one must have diversity of support. I think there is some merit in having some diversity. I think even the National Science Foundation, which has been a most enlightened agency, could fall into error, and there is such a thing as keeping one agency honest by having comparisons with other agencies.

Mr. VIVIAN. Historically, the National Institutes of Health evolved through the departmental structure of HEW and have grown from a very small to a large section of that Department. The National Science Foundation has grown, too. The two are hard to differentiate. If you had a nuclear electronic testing tool as a key part of a testing tool working in biology, one is hard put to know whether it is biological science or scientific biology. To my mind this distinction is not only rather tiresome, but also rather detrimental to the progress of the interweaving of two facets of science. I had thought in the past that NIH might be wiser to be under a similar board as the NSF and more recently that NSF be put under a department as in NIH. Either of these approaches are anathema to large portions of the Washington community. Do you have any option or personal observations on that suggestion?

Dr. WEINBERG. Yes, I have an opinion.

I think it would be a mistake to put NSF and NIH together for the following reason:

I believe that basic research as an overhead on the achievement of an applied mission is a fine way to support basic research, and I see nothing wrong with that. If NIH were in the same box as NSF, then I think you would tend to dilute its mission orientation, that gradually NIH would see its purpose of getting solutions to health problems somehow attenuated and that would be wrong. I think it is very good for NIH to be a mission-oriented agency whose job it is to solve as many health problems as it can and to use basic research as one of the tools in solving these problems.

Mr. VIVIAN. How do you construe the relationship between Public Health Service and NIH?

Dr. WEINBERG. I don't really know too much about the relationship between the two. As I understand it, NIH uses research and investigation, both applied and basic, as a means to achieve the overall mission of the Department of Health, Education, and Welfare. The Public Health Service uses, I guess one would say, engineering and operations to achieve the same thing. But I think it really would be a mistake if we allowed all of our Government agencies to become nonmission oriented. I think it is important that Government agencies remain mission oriented so far as we can identify the missions and that they support basic research as a justified overhead. NSF is different; its mission is science per se; knowledge per se.

Mr. VIVIAN. Does that include biological science?

Dr. WEINBERG. Yes, as I put it in my paper it includes biological science, but because you have such a nice home for the biological sciences, it is not necessary to give very much money to NSF for that specific purpose. I hope the biologists in the audience don't think I am saying that I don't want money for biology. I do.

Mr. VIVIAN. At Oak Ridge you have persons in the social sciences studying the problems of civil defense. Although I have regard for Oak Ridge and have been there before because I am particularly interested in our fusion programs, I was rather surprised to see that you were the center for studies in the civil defense for social sciences. Does this reflect the fact that you perhaps didn't have quite the use for some of your talent that you thought you had?

Dr. WEINBERG. This is a little like the beating one's wife question, Mr. Vivian. One has to be very careful what he says because if he concedes this point, then the next question is, shouldn't his budget be reduced. I should perhaps take this opportunity publicly to say the following: I think the Oak Ridge National Laboratory is up to its ears in very important things to do; I think, however, it is deeply in the national interest that these big Government laboratories that were established for one purpose, always try to deploy against the most important problems.

Generally these important problems that we are deployed against have a strong atomic agency flavor.

In the case of civil defense there are some, notably Dr. Wigner, who believe this is one of the most important public problems that have to be looked at scientifically. Since Professor Wigner was an Oak Ridge alumnus, since he was so very interested in the problem—he had conversations with me and with the Atomic Energy Commission—one thing led to another and finally the Commission said, "Well, it is probably a good idea for Professor Wigner to bring his studies down to Oak Ridge."

So civil defense was a particular case which centered around Professor Wigner.

Mr. VIVIAN. But why Oak Ridge?

Dr. WEINBERG. As I say, because of his particular relation to the Oak Ridge National Laboratory, he knows how things are done there. He likes the way they are done there. He understands them. It was on this account that he persuaded the management of the Laboratory to make representation to the Atomic Energy Commission and the Department of Defense to have a small project started at Oak Ridge.

Of course, the Atomic Energy Commission does have a historical interest in Civil Defense, and therefore, it was not really stretching much of a point for one of the atomic energy laboratories to get into the matter of civil defense.

Mr. VIVIAN. He is certainly a brilliant individual.

Dr. WEINBERG. This is the point. It was a very special case. Here was an opportunity to get one of the foremost scientists in the world deeply involved in what many people, notably Professor Wigner and some of us, visualize as being one of those very unpleasant things, but one that we cannot ignore. We have to look at it very seriously. But I want to say again I really do believe very strongly that these big Government laboratories—if they are to serve the Nation as well as they possibly can—must always try to deploy against the real problems of the Nation; insofar as possible these problems ought to fall within the purview of the parent agency; but in some cases, they don't.

Mr. DADDARIO. Dr. Weinberg, just one question before we proceed to listen to Dr. Kimball. You referred to the National Science Foundation as having become just another science agency. Do you think it is presently structured to handle this growth which you would like to see, taking into consideration its working relationships with the other agencies, and with the Executive?

Dr. WEINBERG. Mr. Daddario, I should make clear in saying the words "just another science agency," I did not in the slightest, mean to demean the fine job of the management or the staff of the National Science Foundation. I think they have done an excellent job.

What I meant to say is there are, as I pointed out in my paper, six or seven other agencies that serve like national science foundations, and some of them are larger than the Nation Science Foundation.

As I visualize it, the National Science Foundation is going to become very much larger. I don't know very much in detail about the Foundation. Both the previous Director and the present Director of the Foundation, Drs. Waterman and Haworth are excellent people, and I have very high regard for them. As far as I understand the general structure of the National Science Foundation, with the National Science Board and a strong Director, I see no reason why that overall structure shouldn't serve a $2 billion agency as well as it does a $½ billion agency.

But I confess that I am not really very familiar with the inner workings of most of the National Science Foundation.

Mr. DADDARIO. You indicate that structurewise it seems to be all right, but that it ought to be reviewed in the event that it needs bolstering up.

Dr. WEINBERG. Probably so, although I want to make clear I don't consider myself an expert on National Science Foundation matters. If you asked me for the structure of the AEC, I could give you a more informed opinon.

Mr. CONABLE. Excuse me.

I understand you to mean that because the National Science Foundation has lost its current status, it is on the same level with the other agencies. Isn't that what you meant when you said it has become just another agency?

Dr. WEINBERG. One of NSF's original statutory missions was to coordinate the work of the other agencies, but the National Science

Foundation wasn't on a high enough level to perform this coordinating role. This coordination function had to be placed in the White House—that is, in the Office of Science and Technology and the Federal Council of Science and Technology.

Mr. DADDARIO. Thank you, Dr. Weinberg.

Our next witness is Dr. Charles Kimball, who is the president of the Midwest Research Institute of Kansas City, Mo.

We are pleased to have you here, Doctor. I regret that we have run a little behind on our schedule. I believe we have something on the order of an hour.

STATEMENT OF DR. CHARLES KIMBALL, PRESIDENT, MIDWEST RESEARCH INSTITUTE, KANSAS CITY, MO.

Dr. KIMBALL. Thank you, sir.

The invitation to appear before this subcommittee expressed an interest in my views as they pertain to the National Science Foundation not-for-profit institute relationship, what is it, and what I believe it should be, plus the supplemental role which the Foundation might play in improving the climate for applied technology.

I am privileged to appear to express my views on these important issues. I believe that I am the only witness in these hearings directly involved in the operation of a not-for-profit institute. While the views I express are my own, nonetheless they do reflect, I believe, a cross section of the viewpoints of other institutes of this type.

My statement is based on the 20-year experience of Midwest Research Institute in contract research, covering a wide spectrum of science and technology for some 1,000 different clients in Government and industry, and corollary personal undertakings, involving technology and economic growth.[1]

It is pertinent here to review briefly the position and significance, in the Nation's research establishment, of the not-for-profit research institutes, especially since the characteristics unique to these institutes are not widely known. The use of the term "not-for-profit research institute" is not specific, for there are many types of nonprofit groups undertaking research. But it is the term usually applied to organizations like Midwest Research Institute. The 10 or so major institutes of this type represent a numerically small, but quite influential, segment of the national research effort. They are a primary type of institution providing the applied science link between those who know modern technology and those who need to know. They are concerned with both generating and communicating knowledge, to governments and industries across the entire realm of the physical, life, and social sciences, as well as engineering.

[1] A joint responsibility for President Eisenhower's Conference on R. & D. for Small Business in 1957.
Chairmanship for the past 3 years of a national engineering foundation conference concerning the social and economic implications of technology.
Recent member of the Department of Commerce Technical Advisory Board.
Discussions with Governors of 12 Midwestern States concerning technology and regional economic growth.
Leadership of the first major NASA contracted technology utilization dissemination effort (since 1961 at MRI).
Member of the governing boards of several colleges, universities, and medical research institutions.

While their role is shared with a number of other groups—the universities, the corporate research laboratories, Government laboratories, and with other research organizations like Rand—the independent not-for-profit institutes are unique as a principal public-interest focus for the application of science and technology to the problems of economic growth and social change.

The Internal Revenue Service categorizes these institutes as tax-exempt organizations. Each has, to varying degrees, received tax-deductible contributions from private industries, individuals, and foundations, largely for plant and equipment. Each is controlled by a board of governors or trustees. All institute employees receive specific stated salaries, have no equity in the institutions, and receive no part of any net proceeds. None of these institutes seek contributions to defray operating costs in any substantial ongoing way. Each seeks to recover all operating costs from its project sponsors, plus an increment which is used to finance research, otherwise unsponsored, to improve experimental facilities, to fund special technical educational programs, and to provide required working capital. In most instances, the increment of income over expense permitted for projects sponsored by governmental agencies is more modest than for projects for industry.

This research institute movement started in 1913, when Robert Kennedy Duncan and Edward W. Weidlein, two young chemistry professors practicing contract research in its early form at the University of Kansas, were brought to Pittsburgh by Richard B. Mellon and Andrew W. Mellon. Thus was started the Mellon Institute of Industrial Research, and a quiet revolution in the world of professional science.

Mellon Institute illustrates very well many of the salient concepts of contract research, particularly in the formative decades from 1910 to 1940, when the corporate use of applied research needed to be convincingly demonstrated to industry. Very few companies had their own laboratories then, and few were prepared to undertake development of new products, processes, and techniques by utilizing the arts and instruments of science.

Next to be founded was Battelle Memorial Institute at Columbus in 1925; then Armour Research (now the Illinois Institute of Technology Research Institute) in Chicago in 1936. In the period 1941–47 several other institutes were founded: Southern Research Institute in Birmingham, Midwest Research in Kansas City, Cornell Aeronautical Laboratories at Buffalo, Stanford Research in Menlo Park, Calif., Franklin Institute Laboratories at Philadelphia, and Southwest Research in San Antonio. More recent organizations of this type are North Star in Minneapolis, Triangle Research in North Carolina, Denver Research Institute, and Spindletop in Kentucky, with several others now forming in Louisiana, Rhode Island, and other States.

These independent institutes have made many important contributions to basic and applied science and technology, and to regional and national issues, serving on one hand the existing, immediate, and practical needs of industry for organized research assistance, and, to an increasing extent in later years, helping meet the needs of Federal and State Governments. They have also stimulated industry

and government thinking, by identifying and developing new approaches to science and technology, pioneering in certain new technical areas of corporate business activities, and acquainting and training management and industry people in the uses and benefits of technology.

A few of the scientific contributions of these institutions provide a notion of their far-reaching effect on the development of significant technology and consequent economic growth. At Battelle, the evolution of the Xerox process is a noteworthy example. Battelle is also one of the leading metallurgy research centers in the world. The Research Institute of Illinois Institute of Technology (formerly Armour), is responsible for the basic development and wide application of magnetic recording. At Mellon, one of our great chemical research centers, research fellows have moved continuously into industry, illustrating the valuable training aspects of these institutes. Some 2,000 Mellon alumni are now in responsible R. & D. positions in government and industry. Mellon also played a key role in developing synthetic rubber during World War II and in industrial hygiene—the control of industrial waste, pollution, and disease-causing factors.

Southwest Research at San Antonio is a leader in the technology of fuels and lubricants, in the field of applied mechanics, and in transmission problems for the gas industry. Southern Research Institute at Birmingham, Ala., has one of the leading cancer chemotherapy groups in the world. Stanford Research Institute is noted for pioneer work in technoeconomics—the concept of combining market realism with technical research. Their long-range planning service is widely used by hundreds of U.S. corporations. SRI's research in electronic data processing resulted in ERMA, an automatic accounting system, which began a revolution in banking services and practices.

The Institute I head—Midwest Research—has made contributions in solid lubricants, in metal fatigue, and in cancer chemotheray, and in the utilization of agricultural products, as well as extensive programs in technology transfer. Our product and process development work for hundreds of companies and agencies has been broadly beneficial to many private and public sectors of the national economy.

These 10 major independent institutes have made many other contributions to society, as well, despite the fact that they represent compositely only a very small fraction of the total U.S. research effort. In 1965 they employed about 11,000 persons. Their research volume was about $150 million, representing less than 1 percent of total R. & D. expenditures in the United States. But their influence in their regions, on the national economy and on technological progress generally has been very much out of proportion to the relatively small dollar activity they represent.

There are many reasons for the effectiveness of these independent institutes. Research is their total activity. They cannot take narrow or provincial approaches. As a result, they must break down the traditional classical impediments between the fields of science for the enlarged benefit of the sponsor whether public or private. Their skills extend from sophisticated basic research to high utility, applied research and technology. Their findings are objective, for they have

no requirement to produce products or processes in volume quantities. Their technical and management people have been intensive users of technology, as well as generators of it, so they bridge the critical gap involved in the transfer of new technology and the economic multiplication of its applications.

At these institutes we find a blending of broad scientific interest with user-oriented values essential to the success of commercial and public missions. Here the man engaging in contract research must visualize clearly the ultimate commercial, economic or mission objectives of his work.

Over the long pull, the very life of these institutes depends on their ability to perform high quality research within competitive cost and time limitations. There is no incentive for quality, efficiency, and utility in research performance so compelling as that of survival in a competitive market. As independent laboratories, we are and have been, for decades, subject to the law of natural selection, and survival of the fittest.

Parenthetically, I note a recent statement attributable to Eric Leinsdorf, director of the Boston Symphony, and quoted in Life magazine. He says:

> To have been graced by providence with special aptitudes and abilities, maybe even with genius, does not at once entitle the bearer to present a bill to the world for remittance.

The role of the not-for-profit research institutes is changing with time, not by reduction of their activities as generators of new knowledge, or in applying science to improve products and processes, for their long record and established responsibilities would preclude a diminution of this effort. But a newer dimension is growing in importance; namely, serving as a catalyst, a coupling agent, an instigator of research, a point of focus for helping industry and government to keep technically posted and alert to change. The institutes serve also as a type of postgraduate school, retraining industrial people in new techniques. These are conducted not on a theoretical basis, but by people who are accomplished performers in their own right, working in an environment of realism, surrounded by real problems.

The research institutes are emerging as an integral part of what is coming to be known as "the knowledge industry," centers of technical authority, trusted sources of information applicable to really significant issues whose solutions may be in technology.

I have inquired of some of the institutes regarding their past relationships with NSF, and what they might be in the future, with a change of Foundation purpose.

With a very few exceptions, there neither is nor has been any appreciable contractual or grant relationship between NSF and these institutes.

The research institutes do not presently regard NSF either as a source of support or as having substantial interest in institute programs even though many institute programs are quite basic in nature. Some of their reasons for this are that NSF has considered its principal role to be the encouragement and partial support, through grants, of academic research. It has not regarded applied research as one of its responsibilities, whereas the research institutes have this as one of their major thrusts. Because of the Foundation's academically oriented

policies, it has been reluctant to depart from the grant type of support which is not compatible with the contract support programs under which the research institutes must operate.

This emphasis on basic research, the university climate or practice of grant support, the educational assistance objectives of the Foundation, all these have possibly been quite appropriate to NSF's operation over the past 15 years. Whether the intent or implied purpose of the original charter was broader than this is not the issue today. We are all operating now in an entirely different era of research, markedly dissimilar to the climate existing at NSF's beginning.

As to NSF's future role—scope and intensity—I would make some observations here about some opportunities I see in the national picture, some of which may be appropriate for an expanded NSF mission.

In making my point, I would not employ the classical distinction between basic and applied research. As an alternative, if one is needed, I would differentiate between "research for need" and "research for opportunity," the former being descriptive of scientific efforts to anticipate change, to protect against loss of corporate market position due to technical obsolescence (such as the role of EDP in automation). This is the kind of research that the textile industry and some office equipment manufacturers failed to do.

"Research for opportunity" is the nondefensive, aggressive type of undertaking, perhaps best categorized by the solid state physics-transistor-electronics communication revolution of the past one or two decades, overtly undertaken at great risk, but with greater possible return. Synthetic fabrics would fit this category, too. But I will not elaborate on these distinctions or get further involved in semantics.

It was suggested by this subcommittee in its invitation that I might have some ideas or observations. I would like to offer one specific suggestion, namely the deliberate development of techniques, curriculums, experiments, and even institutions to provide the Nation with many more effective people serving as "appliers of science."

Given the 15 years of intimate NSF-university relationship, the Foundation might well be the logical national instrument to bring this desired objective into being. Or the independent research institutes could make a considerable contribution out of their long and proven experience in this art of applying science.

Why the emphasis on "appliers of science and technology"? These are the persons who, when properly selected for motivation and when skillfully and purposefully trained (and surely in a multidisciplined way, involving science, engineering, economics, sociology, communications, for example) under practical conditions, would help materially to identify and solve some of the problems relating technology and economic growth discussed by many for the past half dozen years.

My point concerning "appliers of science" would not be at variance with Dr. Teller's earlier statement to this committee that the U.S. effort needs more attention to applied science, and particularly at the graduate level where so much of our effort is now related to pure science. The emphasis seems to be totally on producing Ph. D's, most of whom neither possess nor are they taught entrepreneurial skills. It should be noted that basic research not infrequently emerges from the needs of applied science, as well as the other way around, as is usually expected. And I would add to this that even in the graduate schools

of engineering, this predominantly basic approach seems more controlling than ever, despite our apparent dependence upon engineers as "doers" and as couplers between science and the economy.

Many informed people have stated that the impact of technology on economic growth in this country is not as great as it would first appear or as would be implicitly expected. Many of the reasons for this are obvious and have to do with the basic mission orientation of the bulk of our national research effort. But there are other more subtle reasons, some of which were dealt with very well in the Weinberg report of the President's Science Advisory Committee (officially titled "Science, Government and Information," and dated Jan. 10, 1963). This report, a landmark in the field of information transfer, has as one of its key points the need to distinguish between the transfer of documents, the problem receiving the most attention, and the actual transfer of scientific and technical information. Much would be gained if all graduate students in science, engineering and in business were to study and act upon this terse and important work. One of its key statements is: "Transfer of information is an inseparable part of research and development. All those concerned with research and development—individual scientists and engineers, industrial and academic research establishments, technical societies, government agencies—must accept responsibility for the transfer of information in the same degree and spirit that they accept responsibility for research and development itself." This matter of the literature is only one of the dimensions of the great need for perhaps a new profession—"the application of science."

The utility of science and its resulting technology lies in what can be done with it to expand corporate profits, Government mission capabilities, or regional and national economic growth. Over the past 10 years, a tremendous amount of potentially useful information about science and technology has been generated in this country. Yet we are all concerned about whether we are making adequate use of it for economic growth. Here we have a significant challenge which "appliers of science" could undertake and attempt to understand.

Another set of problems which "appliers of science" could handle is implicit in the obstacles to the fruitful uses of technology, such as the lack of management insight about markets required for the results of research; the unwillingness of some corporate managements to take appropriate risks, which could render existing plant or organization obsolete. As MRI's technology utilization work for NASA has so clearly demonstrated, there is much greater industrial interest in new materials, new processes, new production techniques, because these will require only incremental changes, whereas new products per se could frequently involve greater marketing risks and new plant investments.

Many scientifically trained people are primarily career oriented, seek individual recognition by their peers, with discovery of new knowledge as a principal end in itself. As a consequence, many are unable to fulfill their personal goals within the corporate goal framework.

An "applier of science," knowing that management goals and views are measured by profits and competitive position, would be capable of communicating his findings in the context of their economic utility

(the decisions to use technology, in industry, are largely economic, not technical).

An "applier of science" would help overcome other resistance points to using new technology; old-fashioned building codes being one example; the resistance of some labor groups to automation being another.

He would know that often technology is transferred indirectly, such as by the chemical industry invading the textile industry with its new synthetic fibers.

Specific curriculums directed to the "application of science" might help to bring about a more fruitful rapport between universities and industry, now limited by the unwillingness of some university people to relate their research or academic programs to economic and industrial needs. As these "appliers of science" become more numerous and more skilled, the geographic separation of industry and universities, which is considerable in many parts of the country, would be a less formidable barrier to economic growth than it now is.

I am suggesting that, if NSF is to expand its university programs, it should induce a new dimension of attitude and substance in the university curriculum, which will arouse expectations emphasizing goals and values among scientists and engineers that are consistent with the realities of corporate life and not, as is often the case, that corporate life will be an extension of their graduate school experience. The inclusion in this type of program of more professors with industrial backgrounds would result in younger scientists and engineers developing better insights about the role they will play as employees in industry, and perhaps in public agencies, as well. Some top-flight schools are now underway in such efforts, such as the Sloan School at MIT.

There could be developed, for example, techniques for retraining the technical man, 10 or 15 years out of school, who has already demonstrated entrepreneurial ability, but he may need to be reeducated in his field so he has something to entrepreneur with. The medical profession has done this job very well, as have many graduate business schools.

Internships in the hard sciences and engineering would be very valuable, if they included heavy doses of attention to technical motivation and the economic realism so essential to the success of technology.

Another approach might involve a new use for the sabbatical year by people whose career commitment is to generate knowledge through basic research. Perhaps a year at the transfer points of knowledge would enhance things immeasureably. "Appliers of science" would constitute a sort of impedance match to join the world of today with the academic system.

It will not be easy to find either the right faculty or the right students to develop "appliers of science," or even the right communications mechanisms to bring this about. These people will need training in sociology, anthropology, economics, communications skills. They will have to be trained differently than they are now, with much greater emphasis on bringing technology to more fruitful use.

It may be that graduate business or enginering schools would be most appropriate for starting this sort of effort. Or as a more modest

beginning, special summer institutes for university personnel, including selected graduate students, would be useful, especially if the "faculty" were experienced industrial people.

With today's shortage of skilled people, the Nation can benefit from an intelligent division of labor. In the context of applying science for economic growth, the research institutes might well have a clearly definable role in which they have comparative advantages, being well equipped as knowledge transformers, as I have outlined. Often new knowledge requires years or even decades before it is put to economic use. Transformation of knowledge can often be more effective economically and more capable of acceleration than creation de novo.

We probably don't have time to get into two other issues that are related here: One is the need for better technology in certain backward businesses such as textiles, construction, metalworking, where the appliers I have described would be of far more help than they would be in advanced industries; and the second point, which has been discussed in other hearings, but has a generic relationship here, is the geographical distribution of R. & D. and the effect of NSF on that.

That concludes my statement, Mr. Chairman.

Mr. DADDARIO. Thank you, Dr. Kimball.

You feel that NSF in the future should be active in the transfer of knowledge. Would you recommend that NSF should not confine itself as much as it does to basic research?

Dr. KIMBALL. The simple recommendation I am making here, sir, is this: The transfer of knowledge so far has been carried on by people who seem to have special aptitudes on it on somewhat of an ad hoc basis. I don't know that anybody has been trained to do it particularly because it is too recent an episode in the American scene. I am suggesting that if NSF wishes to extend its activities outside basic research in the universities, it might well foster some intensive training of people to be competent "appliers of science."

Mr. DADDARIO. You also indicate that even though there are reasons for basic research to create knowledge for itself alone, that there is a stimulus that comes to the basic researcher by being involved with some goal, and that he ought not to be removed from that opportunity.

Dr. KIMBALL. Right.

Mr. DADDARIO. Since this is the case and since there should be this energizing, the National Science Foundation should not overlook this possibility.

Dr. KIMBALL. There is much value to having basic research people exposed to applied research people as frequently as possible. I tried to make the point that much basic research stems from the fact that certain applied research problems cannot be solved. So we have to go back to the basic research foundation to get it.

Mr. DADDARIO. What has been your experience that leads you to believe that there ought to be a retraining of people every so often? As I have discussed this with people in industry, there seems to be a tendency for their researchers when they get out of school for the first 2 years to have a tremendous drive toward basic research. After this period, they see that they may be of more value to themselves as well as to their work by correlating it with applied science. Is this included in your recommendation?

Dr. KIMBALL. Yes; and carrying your point further, the people who are beyond the new worker category in research, spending more of their time on applied research, I think they will be better applied researchers if they can get some retreading, 6 or 10 years out of what is new in basic activities. The splendid analogy, of course, is the doctor of medicine, who goes back for the refresher courses for a few weeks every few years, and in a very condensed fashion he learns what is new in medicine. This could well be accomplished by NSF, for example, another kind of special institute, bringing people particularly out of industry and applied research where they may not be adequately exposed to basic research. Now, you can read all about this, you don't have to go back to school, but as I tried to point out with respect to the plethora of information that is published today, a person can't possibly do it himself, it has to be distilled.

Mr. DADDARIO. Part of the barrier seems to be that some of our people develop the idea that the field of the greatest prestige is basic research. Your suggestion seems to be a method toward breaking down this barrier.

Dr. KIMBALL. But for another reason, too. Most of the basic research in the country is funded by the U.S. Government, approximately 60 percent. This brings many of the younger scientists just out of graduate school into working only on public problems. Possibly one of the reasons that technology is making no greater contributions to economic growth is that many of our more proficient scientists are not working on private problems; that is, corporate problems.

Mr. DADDARIO. I was intrigued by the contribution that the nonprofit research institutes have had in the regions where they are located. I would imagine that you have been able to do this because people have wanted positive results from you and you have been able to achieve that end. At the same time, you have built up a field of experience which has been helpful to the Nation.

You have said that we would not have time here to get into the area of geographic distribution. Had you planned to discuss your experience that has shown by directing your efforts with the proper kind of people toward the transfer of knowledge in certain areas of the country you have been able to stimulate activity there, energize the development of programs, and fill in gaps?

Dr. KIMBALL. Yes; and I think it has also demonstrated the close coupling between technology and corporate economic growth. On the issue of research and development distribution as a function of geography, bearing on your point, I would recommend serious attention to emerging centers of competence which are not yet to critical mass. Some very sagacious public funding, not too much in any instance, could be most useful in their full development.

A classical example is the Menninger Foundation at Topeka, Kans., one of the leading psychiatric research and treatment groups in the world, funded largely by private contributions but appreciably enhanced in recent years by the activities of such Federal agencies as the National Institute of Mental Health. This is one example of a private and public funding. There are others throughout the country in other fields which could emerge as well.

I was quoted in Science this week as stating that the part of the country I come from is not too well off economically, and therefore it would get along a lot better if it had more public funding. The quotation of mine was taken out of context, and is something of an oversimplification. The point is that a little Federal leverage could enable many competent groups, whether they are colleges, universities, research institutes or other institutional forms, achieve this critical point of operation.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have a technical question I would like to ask. I am curious to know who owns the title to such organizations as your own?

Dr. KIMBALL. They are public corporations under section 501(c) (3) of the Internal Revenue Code. No individual or group of individuals has or can have a personal proprietary interest in the assets of the corporation. The governing board is usually a group of trustees.

Mr. VIVIAN. Similar to most foundations?

Dr. KIMBALL. Yes, sir.

Mr. VIVIAN. Suppose you wanted to sell the organization, who would then possess the proceeds, presumably the board itself?

Dr. KIMBALL. No; not as individuals. The organization's charter usually provides for diverting the funds to some other public purpose. If the charter is silent, general principles of law reach the same results.

Mr. VIVIAN. Are there any provisions on the sale?

Dr. KIMBALL. Our charter says that if we were to cease operation the proceeds would then be given to a community trust, which again would be another form of tax-exempt organization.

Mr. VIVIAN. To switch back to your relationship with NSF for a few moments, I gather you foresee very little future in your relationship to NSF since you do not mention any particular role?

Dr. KIMBALL. The research institutes and NSF could have a more fruitful relationship than they have had. We have all recognized that NSF has had its hands full in trying to do a rather excellent job with the universities. In the case of some of the smaller institutes, grants for specialized scientific equipment, such as have gone to universities, would have been quite helpful through the years. If NSF gets into the field of encouraging applied science and educating "Appliers of Science," it might well look to the research institutes who have been doing this very effectively for a number of years.

Mr. VIVIAN. For example, you wouldn't mind receiving contracts to provide the framework of education for the career industrial system that you feel is left out at present?

Dr. KIMBALL. Yes. I look at this more as a national problem rather than something that the research institutes are seeking in a new role with NSF. I am just trying to call to the attention of the committee the fact that this problem has to be faced. Whether it is going to be faced by the universities operating under NSF, or the universities operating some other educational activity, is an issue that is perhaps beyond these hearings, but it is a compelling issue in the country.

Mr. VIVIAN. Would you construe your relationship as being much closer to the Department of Commerce if it establishes more aggressive economic development operations than the sciences?

Dr. KIMBALL. Yes; I am quite familiar with what they are doing over there, and I think it is a good thing. The State Technical Services Act I believe will help, although that is oriented largely toward universities.

Mr. VIVIAN. As I recollect, there is no major not-for-profit research institute in the Boston area. Am I correct?

Dr. KIMBALL. There is a very large highly competent and well run institution known as A. D. Little, which is not a not-for-profit organization.

Mr. VIVIAN. I recollect that is a for-profit organization.

Dr. KIMBALL. Yes; and very successful.

Mr. VIVIAN. Stanford has SRI.

How about Los Angeles?

Dr. KIMBALL. SRI has a southern branch at Los Angeles.

Mr. VIVIAN. Is it of any consequence or size?

Dr. KIMBALL. I would think, sir, 200 or 300 people.

Mr. VIVIAN. I note these organizations only because they are in the areas which have grown very rapidly technically. By comparison I note, for example, that Cornell Aero, which I believe is not-for-profit organization such as yours, MRI, and others have not seen the very rapid expansion around their borders which these other communities reflect. I don't think this is the fault of your not-for-profit institutions in any sense, I wouldn't want to construe that. But if you have concentrated heavily on the economic applications of technology, which I think most institutes have done, why has this not reflected in a greater expansion in the surrounding communities?

Dr. KIMBALL. I could cite the case of Kansas City which I know best. When MRI was founded 20 years ago the total technical complement in Greater Kansas City, scientists, engineers, economists, and the like, was approximately 500 people, and today it is approximately 7,500 people. And the institute has been responsible in stimulating much of that growth.

Mr. VIVIAN. So you argue that the success has been very significant even though not perhaps as obvious?

Dr. KIMBALL. Yes. A part of this is the project work institutes do. Another major role is the climate of understanding which institutes set up, as a result of their many public service activities, among community leaders, who have taken many decisive actions.

Mr. VIVIAN. Do you see any reasonable split between the functions of the National Science Foundation and the functions of the Department of Commerce? Do you see any lack of clarity in that split?

Dr. KIMBALL. I don't know NSF as well as I know Commerce, but if I had to make a summary statement about NSF, and it won't be entirely accurate, it would be that it is virtually totally academically oriented and basic research oriented.

Mr. DADDARIO. Will you yield there?

Mr. VIVIAN. Yes.

Mr. DADDARIO. In your relations with the Commerce Department, you have mentioned Dr. Holloman, whom we know very well. Do you see a proper coordination of activities between the Department of Commerce and the National Science Foundation so that there is effective communication and coordination of activities?

Dr. KIMBALL. I am sure they should work with each other. The point I am trying to make here, sir, relates specifically to NSF in an expansion of its university programs. It is now concentrating largely on basic research in what are known as the hard sciences. If this "applier of science" concept is to take root, NSF might well direct its activity more in this direction, at least to a beginning degree, and sponsor educational activities of this sort in business and engineering schools. This would be a new role for NSF.

Mr. DADDARIO. Have you come to this conclusion because of the work you have done with the Commerce Department? Do you see a need for the type of people who could help the Commerce Department to accomplish these end objectives?

Dr. KIMBALL. Not only with Commerce, but with NASA, too, which is pretty deeply and effectively involved in technology utilization. I am trying to look ahead here, perhaps a whole generation, so that the type of people who are involved in this sort of work, 10 or 20 years hence, will be better trained for it.

Mr. DADDARIO. Mr. Brown?

Mr. BROWN. Dr. Kimball, in your statement you noted that possible reasons for the failure to achieve an adequate technology transfer in the area of new product development are the larger problem of rechanneling investment and a reluctance of industry to engage in a major shift of resources resulting from new product development. Could this be a possible factor in the situation in your own area, that there has been a reluctance to make new investment, whereas there is an industrial preference to invest in coastal areas where they might feel the opportunities are better?

Dr. KIMBALL. There is perhaps a higher degree of understanding in the coastal areas, about the venture capital needed that goes with technology. The point I was making earlier is that if we examine the transfer of information from public sources to private use, there is a greater tendency for companies to pick up and use ideas about new techniques, new ways of doing things, new ways of improving their present products and processes, as distinct from going into a whole new line of products, because of the obvious economic factors.

It is becoming quite clear there are many fruitful transfers of knowledge that are being picked up by industry, large and small, but they are principally of the new process, new technique category, rather than a whole new product. It is very difficult to find a product in the public sector that can be turned over intact in this way. The only major one I know that has been of any real consequence has been the jet engine which took 12 years to move from the public to the private sector; radar, for example, on which television depends to a large degree, was not moved from the public to the private sector in one package, rather the technology was moved.

Mr. BROWN. I have had a substantial interest in the technology utilization transfer problem. In conversations that I have had with private companies and entrepreneurs in my own area, there seems to be a difference of opinion as to the value of this, depending upon perhaps the size of the operation. Large corporations seem to be less interested in participating in a technology utilization program perhaps because they see less to gain from it than do small corpora-

tions which are really more adventuresome and are seeking new products or new methodologies. I don't know what the answer to this problem is. I don't know whether your company has had this experience or not.

Dr. KIMBALL. The larger companies practice technology transfer to a considerable degree, but they don't call it that. They have what I call technical intelligence agents working continuously screening and channeling vast amounts of technical information into their own organizations, whereas the smaller company is not able to do this to such a degree.

Mr. BROWN. I think that is correct. There has come to my attention recently what I consider to be an excellent example of technology transfer in an entrepreneural sense involving a cooperative relationship between a university in Los Angeles and a Brazilian university; utilizing personnel from both sources, they have moved into Brazil—and this has occurred in other parts of Latin America—with a program for developing new industry, new technology. This has been done with local private capital.

This program is necessary in an economically underdeveloped area, but equally necessary is a well delineated program that is technically adequate, that does a good job of market research and resources analysis success, and that works successfully in planning or developing economic operations within the framework of an entrepreneural or private enterprise system. Have the nonprofits had any experience with moving into other areas, other than the United States, where they could perform a service in a receptive atmosphere, and at the same time do so in accordance with the kind of economic system that we are interested in furthering?

Dr. KIMBALL. I think the principal practitioners of that sort of activity are Stanford Research and Battelle. Battelle, has two large laboratories in Europe, one in Frankfurt and one in Geneva, which do essentially no government research, either U.S. or foreign government. They are staffed and directed by citizens of those countries. At Stanford Research, some 30 percent of its total economic research activity is in the international field, much of it coupling technology and economic growth.

Mr. BROWN. I am interested in knowing more about a program that could be sponsored by our own Government—whether we call it basic research or not. One of the fundamental problems which confronts our society as a whole, is the economic development of underdeveloped areas, in a pattern or a climate which is favorable to our own system. This is the competition that we are experiencing in the rest of the world, and in which we haven't had a great deal of success. It could be construed as basic research, although not in the physical or the biological sciences, but basic social research to determine how this might be achieved most successfully.

Dr. KIMBALL. I might say we could afford to practice some of that in the United States, in certain parts of the country.

Mr. BROWN. We have underdeveloped parts of this country, too. The real problem does not differ at all in nature——

Dr. KIMBALL. But in degree.

Mr. BROWN. But in degree. I have no further questions.

Mr. VIVIAN. Since this question of moving from the international to the intranational scene has been mentioned, I would like to ask a few questions.

On a matter of regional distribution, do you have any comments on the overall subject of how regional distribution might be measured, determined or accomplished, recognizing the fact that, for example, your own portion of the Nation is not what we could call overendowed with the Federal research funds.

Dr. KIMBALL. Certain institutions in each part of the country, whether educational or other, ought to be singled out either for their proven or their potential competence. They ought to be given reasonable amounts of money, with specifically directed activities, and with cardinal points of accountability every few years. I would strongly suggest that the "competence" concept be implicit in all these. I might say parenthetically that not all the competence is on the east or west coast.

Mr. VIVIAN. Do you have any feeling for any criteria that might be applied, not necessarily in setting up the centers of intelligence, but in the award of the contracts?

Dr. KIMBALL. No; I hope it has dimensions other than political.

Mr. VIVIAN. Yes; do you have any suggestion for dimensions other than political?

Dr. KIMBALL. No.

Mr. VIVIAN. If you had to choose factors that were effective in attracting individuals to certain areas, how would you rank such factors as climate, facilities, cultural advantages, training, and technical activities? Which seem to be the most important?

Dr. KIMBALL. What we have done in Kansas City is to convince people, that had not been there, that it was neither an intellectually nor geographically arid zone. Once having done that, the movement began to proliferate itself and has continued.

Mr. VIVIAN. It wasn't a question of solely salaries?

Dr. KIMBALL. No.

Mr. VIVIAN. But it was establishing an environment where the person felt he would be with his peers?

Dr. KIMBALL. Right.

A Stanford research study shows that there was not a direct correlation or any appreciable correlation between the excellence of universities and the buildup you are speaking of. There is a correlation, but I don't think it is a cause-and-effect relationship.

Mr. DADDARIO. Just one question, Dr. Kimball.

When you indicated the effect your institute had in the Kansas City area, this is not to say that you do not do work throughout the rest of the country. The effectiveness of your institute would be in other places beyond your own region?

Dr. KIMBALL. Yes, sir. Only a small percentage of our total project activity is in the Kansas City area. Last year we worked for sponsors in some 35 States, for example.

Mr. DADDARIO. How has the growth come about in that particular area?

Dr. KIMBALL. It is not simply providing a research service to companies that need it. It is climate setting for the economic use of applied technology, which is implicit in much that I said here today, and in the public service role of MRI.

Mr. DADDARIO. Dr. Kimball, I want to thank you.

I hope that we may be able to send to you and to Dr. Weinberg some additional questions that we have. We are somewhat limited by time in the questioning.[1]

We want to thank both you and Dr. Weinberg for your excellent testimony this morning.

This committee will adjourn until Tuesday next, at 10 o'clock, at the same place.

(Whereupon, at 12:25 p.m., the committee was adjourned, to reconvene at 10 a.m., Tuesday, July 13, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, JULY 13, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

Our first witness this morning is Mr. Francis Keppel, Commissioner of Education.

We are very pleased to have you here, Mr. Keppel.

STATEMENT OF HON. FRANCIS KEPPEL, COMMISSIONER OF EDUCATION; ACCOMPANIED BY FRANCIS A. J. IANNI, ACTING ASSOCIATE COMMISSIONER FOR RESEARCH; HENDRIK D. GIDEONSE, PROGRAM DEVELOPMENT ADVISER, BUREAU OF RESEARCH; AND PRESTON VALIEN, DIRECTOR, PROGRAM SUPPORT BRANCH, DIVISION OF GRADUATE PROJECTS, BUREAU OF HIGHER EDUCATION

Mr. KEPPEL. Thank you, Mr. Chairman. May I introduce to the committee my associates? On my left, Mr. Ianni, whose particular concern has been the research and development programs of the Office of Education which have certain relations with the National Science Foundation; my associate, Mr. Gideonse, also associated with Mr. Ianni; and to my further right, Mr. Valien, who is with the higher education facilities fellowship programs. These are the parts of the Office which I think have the closest relationships with the National Science Foundation.

Mr. Chairman, I have a prepared statement which, if I may, I would like to read perhaps two-thirds of, but skip some of it in order to save the committee's time, if that is satisfactory.

Mr. DADDARIO. That is fine, Mr. Keppel.

(Hon. Francis Keppel's prepared statement is as shown below; his summarization follows:)

PREPARED STATEMENT OF HON. FRANCIS KEPPEL, COMMISSIONER OF EDUCATION

Mr. Chairman and members of the Subcommittee on Science, Research, and Development, it is a pleasure to appear before you today to offer any assistance that I can to your subcommittee's review of the National Science Foundation. May I state at the very outset that the relation between the Office of Education and the Foundation, Dr. Haworth and his colleagues, has become an increasingly close and mutually useful one. As time has passed, we have come to work together in several different areas. The nature of the relationships that have grown up vary all the way from statutory requirements, through ad hoc commit-

tees, to close, informal contacts between officials responsible for administering individual programs in areas of joint responsibility. Wherever the need for cooperation and consultation has arisen, we have found the Foundation a willing partner.

One of the most useful things I think I can do would be to review some of the substantive areas in which the Foundation and the Office of Education have mutual responsibilties, describe what OE's activities are, and outline formal and informal mechanisms of cooperation between the two agencies. There are four areas that should be of particular interest to this subcommittee. I shall discuss each in turn and conclude my testimony with some brief comments on, as you put it in your invitation, Mr. Chairman, some problem areas with which the subcommittee might wish to concern itself.

One of the major areas of mutual responsibility between the National Science Foundation and the Office of Education is support for the construction of graduate facilities in institutions of higher education. The Higher Education Facilities Act of 1963, which the Office of Education administers, provides grants and loans for both graduate and undergraduate facilities in colleges and universities throughout the country. Under title I of the act, grants to 4-year undergraduate institutions are limited to the support of facilities devoted to science, mathematics, modern foreign languages, engineering, and libraries. Graduate facilities, however, may be supported in all fields except the medical sciences (which are already provided for by NIH), theology, and divinity. Buildings to which admission is charged may not be supported.

The undergraduate grants program is managed by State commissions which draw up State plans and make recommendations to the Commissioner of Education on the basis of those plans. Money is allotted to the States according to a formula based on per capita income and college-age population.

The purpose of the graduate grants program is to develop new centers of excellence in graduate studies to increase the number of highly qualified people who can fill the needs of the community in industry, government, teaching, and research.

Title II of the Higher Education Facilities Act has as its mission the improvement of existing graduate schools and assistance in the development of new and developing graduate schools. An important part of this program is the provision for cooperative graduate centers to permit universities to pool their resources for effective work in fields beyond the capability of any one institution.

The graduate grants program is managed by an advisory committee which consists of prominent educators together with one representative each from the National Science Foundation and the President's Science Advisory Committee. Under this program, no State may receive more than 12½ percent of the total appropriation for any one year. In the grants made last June, the Northeast received approximately 14 percent of the grants, the Atlantic coast (from New York to Florida) approximately 30 percent, the Midwest about 21 percent, and the Far West 14 percent. Grants have gone to large and small universities.

The Office of Education facilities program complements the National Science Foundation program. The NSF program is almost entirely concerned with research facilities, while the Office of Education program includes the support of facilities for both teaching and research. In the sciences a proposal not deemed suitable for a grant by NSF because of limited research space projected might be appropriate for a grant under the Higher Education Facilities Act. In general, the Foundation does not make grants for undergraduate facilities such as are provided under title I of the OE-administered Facilities Act.

To insure the exchange of information and a measure of coordination among various graduate facilities programs, the Office of Education this past February established an ad hoc committee with representatives from the Office, NIH, NSF, and NASA to meet once a month to discuss their programs and consider ways of complementing one another's efforts. I think we can show, both as a result of the statutory requirement for membership of an NSF representative on the Adivsory Committee and the activities of the ad hoc committee, that the cooperation on these types of programs has been extensive and productive for both our agencies.

Two major differences exist between the NSF and OE programs besides the Foundation's research emphasis. One is that NSF can make up to 50–50 matching grants based on eligible costs (this means that in fact NSF usually does not pay a full 50 percent of a given building's cost), while the OE grants are

limited to one-third of the eligible cost of the facility. This difference may result in some "shopping around" by universities seeking science facilities in an effort to get the most favorable terms. In view of the sharp enrollment increases in the Nation's colleges and universities, however, the administration is considering seeking a liberalization of the current matching requirement. This change would have the effect of bringing that requirement closer in line to NSF's present policy.

The second difference is that the higher education facilities program provides for other fields in addition to the sciences. Approximately 70 percent of the grants for graduate facilities have been in nonscience fields. This program is the only substantial Federal program providing nonscience facilities.

A second major area of mutual responsibility between our two agencies is the improvement of the qualifications of elementary- and secondary-school teachers. The Foundation's institute program, designed to supplement the training of elementary and secondary school teachers in science and mathematics, is of considerable magnitude. In fiscal 1964, 3,354 elementary school supervisors and teachers received training in 107 institutes. Inservice teachers training at the secondary level, however, represents the Foundation's largest single effort in support of science education. In fiscal year 1964 approximately 35,100 secondary-school teachers of science and mathematics received supplementary instruction as a result of grants for institutes and conferences.

The Office of Education institute programs, under the original NDEA, up to 1964 had served 20,000 elementary- and secondary-school teachers in 386 summer and academic year institutes in modern foreign languages. In December 1963, the Congress amended the act to include institutes for teachers of English to students whose native language is not English; two such institutes were held for the first time during the summer of 1964.

In October 1964, Congress amended NDEA and added a new title XI which authorized a far broader institute program. Under this new title the institutes in modern foreign languages and in English as a foreign language were continued, and seven new types of institutes were added: institutes for teachers of history, geography, reading, English, and of disadvantaged youth; school library personnel; and educational media specialists. The first institutes under this expanded authorization are being held this summer.

In every instance the deepening and broadening of teachers' competence in subject matter is to be emphasized. The act stipulates that the institutes shall be for "advanced study, including study in the use of new materials." Instruction is at the postbaccalaureate level and participants generally have met at least the minimal requirements for State certification. Institutes are also supposed to improve the teacher's instructional practices, and consequently the use of new teaching materials is encouraged. These include the use of new communications media as well as curriculum materials.

The Office of Education takes the initial step toward the establishment of institutes by inviting all eligible colleges and universities to register official interest in the program and to submit completed proposals. A printed guide, a copy of which I have available for the record, is sent to colleges and universities interested in preparing proposals.

Each proposal is read, evaluated, and rated by at least three members of various panels of consultants drawn from the relevant subject area or area of specialization and from all levels of American education. The primary criterion for support is the quality of the proposed program and the staff. The final decision with regard to any proposal, however, will depend partly on the location of the institution. In arranging a program to meet national needs, an attempt is made to insure that each section of the Nation receives adequate attention. Geographic location of the institution as well as the concentration of population in the region concerned are therefore taken into consideration. I have appended to my testimony a series of tables indicating the number of institutes proposed for 1965–66, the number approved, the different types of institutes, and their location by State. As a glance at the tables will show, the institutes are broadly distributed throughout the Nation.

In concluding my remarks on institutes, I want to emphasize that the Office of Education is operating under specific legislative authorization, and that while subject matter is emphasized, stress is also laid on the improvement of the teaching skills of participants with respect to the subject under study.

A third major area of mutual responsibility deals with graduate fellowship programs. Under the original provisions of title IV of NDEA, fellowship support was restricted to doctoral programs which were either new or expanded.

Between 1959–64, the 3-year fellowships were allocated to specific study programs. With only 1,500 new fellowships to distribute each year but with a growing number of qualified institutions and programs applying for them, competition became increasingly keen. The policy, therefore, was to shift support after 4 years to other new or expanded programs of promise and potential in order to distribute the available assistance as equitably as possible. It was never possible, however, to support all qualified programs or to give adequate support to the approved program.

FIGURE 3

The emphasis of the title IV program came to rest mainly upon graduate departments at developing institutions which could qualify in the new or expanding category, and upon expanding departments and new interdepartmental programs at established universities. Moreover, the act stipulated that fellowship allocations be made exclusively on the basis of programs which were devoted to preparing college teachers and which were approved by the Commissioner of Education. This concern with programs rather than institutions tended to focus title IV attention at the departmental level, while the limited duration of support encouraged narrow rather than broad gage academic perspective and planning.

The 1964 amendment to the National Defense Education Act fundamentally altered this state of affairs in several ways:

1. The number of fellowships was doubled for 1965–66 (i.e., from 1,500 to 3,000), increased to 6,000 for 1966–67, and to 7,500 for each of the 2 following years (through 1968–69).

2. Awards vacated by the fellowship recipient (voluntarily or involuntarily) were to be made available to the institutions for reallocation for the remainder of the original period of the award.

3. Most important, half of the fellowships for fiscal year 1965, and two-thirds thereafter, were released for allocation to doctoral programs which were not necessarily new or expanded, but which had the capacity to enroll additional students with existing staff and facilities.

Provided with the legislative amendment extending through 1968–69 and a supplemental appropriation for 1965, the title IV program needed a new policy—both for the immediate distribution of the 1,500 additional awards in 1965–66, and for the amended fellowship program as a whole.

The policy recommendations approved by the title IV Advisory Committee provided that future support be allocated in concentrated blocs of fellowships. The fellowship blocs will be distributed not only to new or expanded programs, but will also be directed to fill unused capacity in programs of quality wherever they might exist. The shifting and limited support fixed upon individual study programs thus gave way to a policy promoting institutional perspective and integrity for a development of graduate education nationwide. The encouragement of academic excellence was a foremost consideration in these policy deliberations. It was affirmed that the primary field for expanding doctoral study lay among those institutions whose graduate schools have experienced relatively recent but dynamic development and had the basic quality, resources, and leadership to make significant strides toward major graduate school status.

Of the total 1,500 supplementary awards for 1965–66, 210 fellowships were distributed among the new or expanded programs which had been recipients of the original 1,500 awards in the regular competition during the summer of 1964. But with regard to the remaining 1,290 fellowships, highest priority was set on programs previously ineligible for support—those which were neither new nor expanded—but whose capacity for doctoral students was as yet unrealized. Moreover, in order to initiate the policy of bloc support, it was decided to allocate no fewer than 20 fellowships to each successful institution. This meant that no more than 64 institutions could receive additional support for 1965–66.

Applications were received from 156 institutions; only 44 were selected for support. For the first time, the competing universities were required to make a full statement of institutional plans toward expanding graduate programs over the next 5 years. It was incumbent upon them to show a clearly conceived institutional scheme for utilizing a large number of fellowships effectively.

No minimum allocation has been set in the competition now underway for 6,000 fellowships in 1966–67, but the policy of giving bloc support to institutions exhibiting the promise of excellence will be a foremost consideration. Primary attention will be directed to fostering the potential of universities whose dynamic character places them within reach of the first rank in the foreseeable future. Institutions of established and acknowledged distinction will be given reasonable assistance to expand to full capacity but will be assigned a secondary priority. Special priority is assigned to institutions whose application for support may be approved in toto, thereby rewarding the university whose own self-appraisal reveals the high quality of doctoral programs selected for inclusion in its proposal.

The integrated development of graduate study, based upon thoroughgoing and critical introspection on the part of the university, is the key objective of the expanded title IV program. The institutional allowance of $2,500 annually for each title IV fellow on campus may be utilized by the graduate dean or academic

vice president as an instrument of academic advance, to be invested in accordance with the stated objectives and aims of the university for development of its graduate study capability.

The Office of Education has pursued this policy deliberately in order to achieve two purposes through the development of a single program. Not only will the fellowships significantly increase the number of graduate students entering college teaching, but the institutional support that accompanies the fellowship award will be distributed in such a way as to strengthen graduate education across the Nation. For the use of the subcommittee, I have appended to my testimony tables showing the areas of fellowship award for fiscal 1965, and the regional and State distribution.

Allocation of 3,000 fellowships by academic field

	Number	Percent
Humanities	730	24
Education	210	7
Social sciences [1]	862	29
Subtotal	1,802	60
Biological sciences	381	13
Physical sciences	548	18
Engineering	269	9
Subtotal	1,198	40
Total	3,000	100

[1] Includes history whereas NSF does not. In past years, history fellowships have totaled about 12.5 percent of the total for social sciences.

1962–63 doctorates, 1965–66 title IV fellowships, and 1960 population percentages by geographic region

	Percent of 1960 population	Number of doctorates earned, 1962–63		Number of 1965–66 title IV fellowships	
			Percent		*Percent*
Office of Education regions	100	12,820		3,000	
1. New England	6	1,334	10	316	11
2. Mideast	21	3,059	24	553	18
3. Great Lakes	20	3,297	26	630	21
4. Plains	9	1,167	9	317	11
5. Southeast	22	1,210	10	485	16
6. Southwest	8	668	5	185	6
7. Rocky Mountains	2	404	3	94	3
8. Far West	12	1,681	13	420	14

NOTE.—In regions awarding relatively few doctorates, support from the title IV program has been high in proportion to their actual doctoral production. In the past 6 years, the single region that has received more title IV fellowships than any other is the Southeast, with 2,331 awards or 20 percent of all the fellowships. In recent years this region has awarded less than 10 percent of the Nation's doctorates. If it is assumed that low doctoral production is an indication of a shortage of facilities for graduate study, the strongest relative impact of title IV assistance is in those geographic regions where the shortage of facilities is the greatest.

In the Mideast and New England, heavy doctorate producing areas, title IV awards have gone, for the most part, to the newer or less prestigious graduate schools. In New England, for example, approximately half of the fellowships have gone to schools outside Boston, Providence, and New Haven. In Massachusetts, 75 percent of the awards have gone to schools that are not members of the Association of Graduate Schools. In New York, approximately half of the fellowships have gone to such schools.

FIGURE 6

Coordination with NSF on the fellowship program has been informal rather than official, but OE programs do operate with considerable knowledge of counterpart efforts at NSF. As a matter of fact, several of the Office officials have actually worked in the NSF programs. In addition, frequent informal meetings have been held between the staffs of the fellowship programs and, when the Office of Education panelists were briefed on the new policy, NSF officials responsible for training programs were present at the meeting. When the fellowship program changed its emphasis to long-range planning in the interest of strengthening graduate education, Office of Education officials consulted with their counterparts in NSF responsible for the science development program which bears, of course, some strong similarity to the new aims of OE's fellowship program.

The final area of mutual responsibility arises from the several pieces of legislation authorizing the Office of Education to conduct research in education. Research programs are conducted in the following areas: (1) handicapped children and youth, (2) the teaching of modern foreign languages, (3) new educational media, (4) adult and vocational education, and (5) cooperative research which is conducted by all parts of the education community and which researches problems generally in the field of education. The emphasis on research and development as a primary means to the achievement of quality education is only a few years old and it is in part to the Foundation's support of course content improvement efforts in the sciences that we owe the expansion of OE educational research activities.

We have been successful in involving individuals and institutions from every part of the educational and scientific community. The Office has supported 3,000 contracts and grants for research in education. These grants have gone to institutions and agencies in every State of the Union. The cooperative research program is the largest and most extensive of the Office's research programs. While the other research programs are directed to specific problem areas within education, for example, vocational education, cooperative research is authorized to conduct research, surveys, and demonstrations in the entire field of education. Its procedures may be taken as typical of other OE research programs.

Research proposals are forwarded for review to appropriate panels of research scholars. These reviewers evaluate the proposal according to the following criteria: (1) the potential significance of the proposed project for education; (2) the soundness of the research design or operational plan; (3) the competence and availability of personnel and facilities to carry out the proposed project; and (4) the economic efficiency of the proposed project. If a sufficient

number of field reviewers approve the project and give it a high priority, it is forwarded to the Research Advisory Council. The Research Advisory Council is composed of distinguished people drawn from all parts of the educational community who consult with, and advise the Commissioner on, the conduct of the entire research effort of the Office of Education. Proposals which meet the standards of this dual review are recommended to the Commissioner for award.

Generally speaking, the burden of identifying areas in need of research and development rests with individuals and institutions who request support from the USOT. Through this combination of individual and independent initiative and careful reviewing procedures, research has been supported in many fields within education. Basic and applied research studies have included controlled experimental research, surveys, correlational, methodological, and case studies, and developmental, and historical studies. Among the variety of educational topics covered are mental retardation, child development, aptitudes, and abilities, cognitive studies, educational psychology, cultural deprivation, the roles of teachers and school administrators, the development of language and reading skills, programed instruction, guidance and counseling, and school finance. We have also provided support for basic research in the behavioral and social sciences.

One major effort of the cooperative research program is its curriculum improvement program. A project in this program may deal with a curriculum, a course, a subject, or any aspect of these. It may cover any subject field at one or more grades or levels of education from preschool through higher and adult education. The curriculum improvement program of the Office represents an attempt to approach this area as an integrated whole. The Office is also conscious of the need to relate its curriculum improvement projects to other efforts in the field both up and down the grade levels and across the related disciplines. For these reasons, the Office attempts to identify and then to stimulate projects to fill gaps which may be created by the development of specialized courses or curriculums or to provide alternatives to already existing curriculum improvement efforts.

In order to insure that the efforts of the Office of Education and the National Science Foundation in the curriculum area complement each other, several coordinating practices are in effect. Cooperation has been institutionalized by the appointment of an NSF staff member to the OE curriculum improvement review panel since the initiation of the curriculum improvement program. NSF and OE staff members have conducted joint site visits to investigate the research potential of proposed project locations. The Office and NSF jointly review and fund proposals which relate to both agencies.

These, then, are the major areas of mutual responsibility: the construction of graduate facilities in institutions of higher education; fellowships for future college teachers; teacher institute programs; and certain kinds of research in education. I have tried to demonstrate the effectiveness and importance of the coordination that we have been able to achieve between the two agencies. Your invitation to testify also requested that I address myself to a discussion of areas where it might be desirable to consider in greater detail the nature of the relationship between NSF and OE programs.

In addition to some differences already discussed, questions ought to be raised about the efforts to improve school curriculums through the support of course content improvement projects under NSF and curriculum improvement projects under cooperative research in OE. As both agencies continue to undertake this kind of activity in different disciplines, it will be necessary to oversee cooperatively activities along the whole range of curriculum improvement to insure the preservation of pluralistic, diverse, and multiple approaches to curriculum and the enhancement of the spirit of experimentation at the local level. Increasing attention will have to be paid to the problem of how schools will "mix and match," if you will, the various courses being developed and indeed whether or not this is possible at all. Coordination of Federal activities in support of curriculum improvement is necessary to assure the continued existence of alternative choices for local policy planners without at the same time fomenting curricular anarchy in the Nation's schools.

A second question, closely related to the last one, involves the relationships between NSF and OE institute programs and between both and the curriculum improvement programs. It is well established that to be truly effective teachers must be trained in the use as well as renewed with regard to the content of the new curriculum materials. Both NSF and OE now operate major institute programs. As curriculum improvement efforts become more sophisticated, better efforts will have to be made to insure that teachers are able to adopt varieties of

new practices, and adapt their teaching to fit the needs of children moving from school to school and program to program. Little attention has been paid to this need in its larger ramifications, and although some NSF institutes have paid attention to the problems of teaching the new content, the NDEA institutes have perhaps more consistently concerned themselves with the teaching of the subject while continuing to place major emphasis on the subject matter itself.

Before completing this testimony, I would like to reiterate my earlier statements of appreciation for the amount and kind of assistance and cooperation we have received from the Foundation. It has in many ways made our task easier and contributed to the improvement of both our programs. Thank you.

Mr. KEPPEL. I am sure you realize it is a great pleasure to appear before you today. I would like to state at the very outset that the relation between the Office of Education and the NSF, Dr. Haworth and all his colleagues, has been increasingly close and useful. I might say I have been on my job for 2½ years, and this relationship has become more constant and intimate, formal and informal, every month.

The nature of the relationships that have grown up vary all the way from statutory requirements, through ad hoc committees, to close, informal contacts between officials responsible for administering individual programs in areas of joint responsibility. Wherever the need for cooperation and consultation has arisen, we have found the Foundation a willing partner.

Mr. DADDARIO. Will you discuss how these informal contacts work? During these hearings, we have had some discussion concerning the importance of such things as picking up the telephone.

Mr. KEPPEL. I will touch on it later program by program, sir, but not quite in the way you asked the question. Let me see if I can give some examples in the last month which, if I may say so, were not connected with these hearings. The Office of Education is undergoing a substantial reorganization because of its very rapid growth in the last 2½ years, and just yesterday, as part of a regular program that Dr. Haworth and I have, one of my colleagues and I went over to review the administrative changes with Dr. Haworth and his colleague with respect to why this change took place or another change took place. I think this is about the third or fourth routine meeting. Second, there is an informal interchange on advisory committees, which apply to some programs, but where it is not statutory, Mr. Chairman, we in effect accomplish the same thing in my office by asking an NSF staff member to attend the appropriate meeting even though it may not be in the statutes of our law and vice versa.

Finally, you indicated an interest in the kind of telephoning that goes on. Mr. Ianni could indicate that our office as a matter of pure routine whenever a proposal comes in in the mathematics or science area, a new curriculum or a program that affects so-called educational research, it is just routinely sent off for comment to NSF. I don't think it requires your action?

Mr. IANNI. No, it goes over.

Mr. GIDEONSE. And we receive from them proposals in geography, sociology, and so forth routinely.

Mr. DADDARIO. Who initiates that? Does it have to be cleared at various levels?

Mr. IANNI. No. Actually when the proposals come in, if they are in areas of concern to the Science Foundation they are automatically sent over by our proposal receiving unit in the office.

Mr. KEPPEL. I may say, sir, that both with Dr. Waterman and Dr. Haworth I have asked this point. We concluded that the best way to have this done was to have it routinely done, not going up to the front office in either case.

Mr. DADDARIO. Do people on the same level of activity and working in the same area get together and eliminate whatever problems there might be or do they ask for advice in regard to problems?

Mr. KEPPEL. This is the informal part which from my point of view is the most important. I would like to make this public statement now. The Office of Education when it came to new curriculums and a good many of the teacher training institutes and that sort of thing had a lot to learn from NSF. In effect it sounds like the Office of Education had to learn about education from the National Science Foundation. If that is what it sounds like, that is what I mean, Mr. Chairman. We could learn a lot from NSF on institutes, how to handle fellowships, Ph. D. fellowships, how to handle the program that Mr. Ianni is particularly concerned with on new curriculums. This was the kind of exchange that was more on our side, more to our benefit in the last few years than it was to NSF's, frankly.

I think, Mr. Chairman, there are four areas that would be of particular interest to the subcommittee. If I may just turn to each one in turn and then following your request, Mr. Chairman, point to certain problem areas, I believe is the phrase you used, with which you might wish to concern yourselves. One of the major areas of mutual responsibility between the two agencies is support for the construction of graduate facilities in institutions of higher education. The Higher Education Facilities Act of 1963 which the Office of Education administers provides grants and loans for both graduate and undergraduate facilities in colleges and universities throughout the country. Under title I of the act, grants to 4-year undergraduate institutions are limited to the support of facilities devoted to science, mathematics, modern foreign languages, engineering, and libraries. Graduate facilities, however, may be supported in all fields except the medical sciences—which are already provided for by NIH—theology, and divinity. Buildings to which admission is charged may not be supported.

That means stadiums and that sort of thing.

The undergraduate grants program is managed by State commissions which draw up State plans and make recommendations to the Commissioner of Education on the basis of those plans.

If I may say so, that means that the State commissions are the ones that are setting the priorities as to which institution gets the matching grant. Money is allotted to the States according to a formula based on per capita income and college-age population.

The purpose of the graduate grants program is to develop new centers of excellence in graduate studies to increase the number of highly qualified people who can fill the needs of the community in industry, government, teaching, and research.

That is almost a quote from the act, sir.

Title II of the Higher Education Facilities Act has as its mission the improvement of existing graduate schools and assistance in the development of new and developing graduate schools. To give you a sense of the order of magnitude, title I for grants is $230 million.

That is the undergraduate physical expansion. Title II, which is the graduate, is $60 million. In addition to this, you have a loan fund, which is title III, of $169 million. This is the order of magnitude, Mr. Chairman, that we are dealing with annually. One important part of the title II, the graduate program, is the provision for cooperative graduate centers to permit universities to pool their resources for effective work in fields beyond the capability of any one institution.

The graduate grants program is managed by an advisory committee which consists of prominent educators together, and here we get to statutory relationships with NSF, with one representative each from the National Science Foundation and the President's Science Advisory Committee. Under this program no State may receive more than 12½ percent of the total appropriation for any 1 year. In the grants made last June, the Northeast received approximately 14 percent of the grants, the Atlantic coast—from New York to Florida—approximately 30 percent, the Midwest about 21 percent, and the Far West 14 percent. Grants have gone to large and small universities.

As you can see, Mr. Chairman, this has only been going on since the appropriation was received this fall.

This program I think it is fair to say complements the NSF program. The NSF program is almost entirely concerned with research facilities, while the Office of Education program includes the support of facilities for both teaching and research. In the sciences a proposal not deemed suitable for a grant by NSF because of limited research space projected might be appropriate for a grant under the Higher Education Facilities Act. In general, the Foundation does not make grants for undergraduate facilities such as are provided under title I of the OE-administered Facilities Act.

To insure the exchange of information and a measure of coordination among various graduate facilities programs, the Office of Education this past February established—this is another type of relationship, an ad hoc committee, this is not by statute—with representatives from the Office, NIH, NSF, and NASA to meet once a month to discuss their programs and consider ways of complementing one another's efforts. I think we can show, both as a result of the statutory requirement for membership of an NSF representative on the Advisory Committee and the activities of the ad hoc committee, that the cooperation on these types of programs has been extensive and productive for both our agencies.

Two major differences exist between the NSF and OE programs besides the Foundation's research emphasis. One is that NSF can make up to 50–50 matching grants based on eligible costs. I may say, sir, I understand from Dr. Haworth that NSF does not pay a full 50 percent of the amount of a building's cost. That is with relation to what you describe as eligible, what is an eligible cost under the NSF. In any case it can make up 50–50 grants, while the Office of Education grants are limited to one-third.

In view of the sharp enrollment increases in the Nation's colleges and universities, however, the administration is considering seeking a liberalization of the current matching requirement. This change would have the effect of bringing that requirement closer in line to NSF's present policy.

I understand what that verb means, "shopping around" in Washington. I don't know that it means any harm.

Mr. DADDARIO. You mean it is done on occasion?

Mr. KEPPEL. I think so. I sometimes thought that academic freedom rested between Government agencies. In view of the sharp enrollment increases in the Nation's colleges and universities, however, the administration is considering seeking a liberalization of the current matching requirement. This change would have the effect of bringing that requirement closer in line to NSF's present policy.

Mr. DADDARIO. You have raised the point that NSF does not pay up to the full 50 percent and have referred to the one-third as not being enough. Is it your policy to use the entire one-third in each instance?

Mr. KEPPEL. It is actually not within our power, sir. The State commissions have the power to decide within the State the extent to which the Federal funds shall be used for matching, that is, the language of the act reads up to one-third, in a good many of the States, I have forgotten how many, say up to 25 percent, they have so many applications, they have decided that the matching funds are available to institutions within the State, and they can spread the expansion program.

Mr. DADDARIO. You have no control whatsoever with reference to their discussion as to the amounts of money that may be used up to two-thirds?

Mr. KEPPEL. They send us in a plan for carrying out the act of Congress. We review the plan and the criteria. If those plans and criteria, which might well include in some States, I am not saying 33⅓ but up to 25, but if it meets the act, we approve the plan, and then the individual decision, institution by institution, are made by the State commission. And there we are in effect just routine, we don't question that.

Mr. DADDARIO. If the one-third should be increased to 50 percent, would that same condition apply, that it would be their prerogative rather than yours?

Mr. KEPPEL. That, of course, would depend, Mr. Chairman, on what the Congress wished to do with the language. I think we would recommend that the Congress consider language up to 50 percent rather than a flat amount.

Mr. DADDARIO. Up to 50 with certain additional powers in your hands?

Mr. KEPPEL. I don't think we have been thinking of that, sir, it is the first time I believe in higher education that the State commission technique has ever been used, and while I can't pretend to be an expert on it, Mr. Valien knows much more than I, I think it is working remarkably well. Rigidity in matching has shown itself in one example to be an unhappy circumstance. In the Higher Educational Facilities Act, part of the act refers to junior colleges or community colleges and requires that the matching be a flat 40 percent. The intent of Congress was clearly to encourage the development of junior colleges. Perhaps Mr. Brown will recall this. It was to give you a break. Well, the way it actually worked out in California and a couple of other States, the 40 percent, instead of freeing the prisoner locked him up tighter, if I can put it that way, because it had to be

40 percent and the nature of the proposals that came in were such that it ended up, for reasons that will take me perhaps too long to explain, with only one institution getting the support when there are a lot more asking. The State commission pleaded with us to give them flexibility, to reduce it from 40 to 30, which by law we could not.

Mr. MOSHER. It seems to me, in our State that this discretionary authority would be very valuable and very important.

Mr. KEPPEL. We would plead for it. In fact, we are going up to plead for discretionary authority up to 40 percent by amendment in the junior colleges.

Mr. DADDARIO. Your recommendation then supports the procedure but asks for more flexibility.

Mr. KEPPEL. Let me call it "technical amendment" at this point. I think that is what we are asking for, in public junior colleges.

Mr. ROUSH. Mr. Chairman, when the State commissions ask for matching funds only up to, say, 25 percent, is this caused by a limitation on funds or is it caused by limitations of authority?

Mr. KEPPEL. Funds, sir.

Mr. ROUSH. Wouldn't the first step then be to increase the amount of funds available rather than to increase the percentage of matching authority?

Mr. KEPPEL. I will feel better qualified to answer this very shrewd question, Mr. Chairman, after more experience. We have had one go around with the States since it has been in effect since November. What you are speaking to is really what is available in matching, either State money or private money. I am not sure I can answer that question well. Actually, the House subcommittee has proposed, and has now I believe waiting before the Rules Committee, very nearly a doubling I believe of the undergraduate figure on the assumption that there is that much matching. Obviously, my hopes are with it, but I would feel better, sir, answering that question a little later.

Mr. ROUSH. That is all, Mr. Chairman.

Mr. KEPPEL. The second difference in this higher education facilities program, other than the 50–50 matching, is, of course, that this higher education facilities program provides for other fields in addition to the science. You might be interested that approximately 70 percent of the grants for graduate facilities since it was funded 8 or 9 months ago have been in nonscience fields. This program I may say is the only substantial facilities Federal program provided in the nonscience fields.

A second major area of mutual responsibility with NSF is the improvement of the qualifications of elementary and secondary school teachers. You may recall, Mr. Chairman, I mentioned what the Office of Education had learned from NSF with respect to their institutes for such teachers in other fields. The NSF institutes program is designed to supplement the training of elementary and secondary school teachers in science and mathematics and is of course a big program. In fiscal 1964, 3,354 elementary school supervisors and teachers received training in 107 institutes. Inservice teacher training at the secondary level, however, represents the Foundation's largest single effort in support of science education. In fiscal year 1964 approximately 35,100 secondary school teachers of science and mathematics

received supplementary instruction as a result of grants for institutes and conferences.

The Office of Education institute programs under the original NDEA up to 1964 had served 20,000 elementary and secondary school teachers in 386 summer and academic year institutes in modern foreign languages. This was the original focus of the NDEA in teacher training.

In December 1963, the Congress amended the act to include institutes for teachers of English to students whose native language is not English; two such institutes were held for the first time during the summer of 1964.

In October 1964, Congress amended NDEA and added a new title XI which authorized a far broader institute program. Under this new title the institutes in modern foreign languages and in English as a foreign language were continued, and seven new types of institutes were added: institutes for teachers of history, geography, reading, English, and of disadvantaged youth; school library personnel; and educational media specialists. The first institutes under this expanded authorization are being held this summer.

Here I think the intent is close to the NSF intent, that is, the deepening and the broadening of the teachers' competency in the subject matter is to be emphasized. The act also stipulates that the institutes shall be for "advanced study, including study in the use of new materials."

An example might be in modern foreign languages—the new methods of teaching modern foreign languages with laboratories and that sort of thing.

Instruction is at the postbaccalaureate level and participants generally have met at least the minimal requirements for State certification. Institutes are also supposed to improve the teacher's instructional practices, and consequently the use of new teaching materials is encouraged. These include the use of new communications media as well as curriculum materials.

We go at this, I think, much the way NSF does. We invite all eligible colleagues and universities to register official interest in the program, and I have one of these documents for the committee's record in case the committee should be interested as to what is distributed to the colleges and universities to make such applications. And we follow, I suspect, a pattern not unlike the NSF's pattern. On the top of page 6 I go through the machinery here. I think the members of the committee, I am not sure how my testimony is before you, Mr. Chairman, but on mine at least immediately following this page on 6a and 6b there are some tables that show the number of proposals. As you can see from figure 1 (p. 298) we are forced to select a little less than half, can fund a little less than half of the proposals and figure 2 (p. 298) would show you the emphasis on the varying programs in history and geography. I would guess, sir, the only point where there might be a possible overlap, if that is the word, or relation with NSF would be under the heading of geography. That has been easy enough to work out. Finally, in figure 3 (p. 299) you will see the States in alphabetical order, and there have been these institutes. This is for the current academic year. We show they are scattered pretty widely across the country.

Mr. DAVIS. Dr. Keppel, I notice in figure 1 (p. 298), and in your testimony when you were referring to categories you start out with the well known subjects such as history, geography, reading, English, and then you say "disadvantaged youth." Does that mean that you study about disadvantaged youth?

Mr. KEPPEL. This, by the way, I think is a phrase taken directly out of the act that tells us to give institutes—the purpose here is the kind of teacher-training that one might give to a teacher who is going to be assigned to a slum school. This means really trying to teach them something about the motives, the homelife, the attitudes of children——

Mr. DAVIS. It is an orientation course?

Mr. KEPPEL. That, plus, I think, the psychologist and the sociologists—I had better turn to Mr. Ianni, whom I always tease about being wholly unable to understand the language of the social scientist.

Mr. DAVIS. He has plenty of company.

Mr. KEPPEL. I would say that the sociologist and the psychologist can give information to a future teacher as to what makes these students particular or not particular. These institutes are for that purpose.

Mr. DAVIS. That problem would no doubt vary in different parts of the country?

Mr. IANNI. Very much so. By the way, this is not restricted to social science, even in such areas as language; for example, there are specialized techniques which have to be used by children whose language background is not the same as the typical middle-class child.

Mr. KEPPEL. The third area of mutual responsibility deals with graduate fellowship programs. Each one providing the institution with $2,500 as well as the individual who won it.

That was established in 1958, got going in 1959 for the first time. The intent of Congress was very straightforward. It was fellowship support restricted to doctoral programs which were either new or expanded. The policy followed in order to keep spreading was to shift to a new institution in order to distribute the available assistance as equitably as possible. There were far more applicants than we could possibly fund.

Mr. ROUSH. I am not sure I quite understand the shift. The shift was from what to what?

Mr. KEPPEL. In a sense I haven't quite gotten to that. Let me come to that. The Congress in 1964 amended the NDEA fundamentally altering its program. There were three aspects to it that we should bring to your attention: No. 1, the number of fellowships to be awarded, assuming funding, was doubled; that is, it went from 1,500 in 1964–65 to 3,000 in 1965–66, and then for 1966–67 we are talking academic years here—from 3,000 to 6,000, and then 7,500. This means five times greater increase. That is change No. 1.

No. 2, any award vacated by a fellowship recipient was to be made available to its institution for reallocation.

No. 3, perhaps most important, the Congress decided that half of the fellowships for fiscal year 1965 and two-thirds after fiscal year 1965, that obviously is the coming fiscal year, were to be released for allocation to doctoral programs which were not necessarily new and

expanded but doctoral programs which had the capacity to enroll additional students with existing staff and facilities.

Clearly then the title IV program needed a new policy, both for the immediate distribution of 1,500 fellowships which we had already in hand last summer and the 1,500 new fellowships that were coming in as a result of a supplemental appropriation. What we did, Mr. Chairman, we had a statutory advisory committee, which we will be glad to enter into the record, whose advice the office sought as to what to do with shift in policy. In addition we asked a group of eminent university people and association people—let me just read a few names; Mr. Arlt, the president of the Council of Graduate Schools of the United States; President Brewster of Yale; President Harrington of the University of Wisconsin; including Dr. Riecken, the Associate Director of NSF as a member of that group, I can go on—to propose from the universities' point of view and NSF's and others what would be the most sensible program of carrying out this almost quantum increase. The recommendations of this group of university presidents were also reviewed by the statutory advisory committee and what I now speak to, sir, is the result of those steps. The policy recommendations by this group provide that future support of these Ph. D. fellowships be allocated in concentrated blocks of fellowships. The fellowship blocks will be distributed not only to new and expanded programs; that is the 1,500, but will also be directed to fill the unused capacity in programs of quality wherever they might exist. The shiftings and limited support fixed upon individual study programs thus gave way to a policy promoting institutional perspective and integrity for a development of graduate education nationwide. The encouragement of academic excellence was a foremost consideration in these policy deliberations. It was affirmed that the primary field for expanding doctoral study lay among those institutions whose graduate schools have experienced relatively recent but dynamic development and had the best quality, resources, and leadership to make significant strides toward major graduate school status.

Of the total 1,500 supplementary awards for 1965–66, 210 fellowships were distributed among the new or expanded programs which had been recipients of the original 1,500 awards in the regular competition during the summer of 1964. But with regard to the remaining 1,290 fellowships, highest priority was set on programs previously ineligible for support—those which were neither new nor expanded—but whose capacity for doctoral students was as yet unrealized. Moreover, in order to initiate the policy of block support, it was decided to allocate no fewer than 20 fellowships to each successful institution.

In thinking of this, Mr. Chairman, it might be not only worth thinking of those 20 Ph. D. candidates but also 20 times $2,500 or $50,000 to the institution.

Incidentally, this meant that no more than 64 institutions could have received additional support for 1965–66. Actually, 44 were selected. The institutions were asked to make a full statement of their institutional plans toward expanding graduate programs over the next 5 years. I emphasize this point because the program was initiated through collaboration with Mr. Riecken, who is very important at this point. In the academic year 1966–67 we will be entering into

a situation where we have not 3,000 but 6,000 fellowships. The policy of giving block support to institutions exhibiting promise of excellence will be of foremost attention. Primary attention will be directed to fostering the potential of universities whose dynamic character places them within reach of the first rank in the foreseeable future. Institutions of established and acknowledged distinction will be given reasonable assistance to expand to full capacity but will be assigned a secondary priority.

May I emphasize that, reasonable assistance is offered institutions to expand to full capacity because all of them are not necessarily to full capacity in all academic fields. Special priority is assigned to institutions whose application for support may be approved in toto, thereby rewarding the university whose own self-appraisal reveals the high quality of doctoral programs selected for inclusion in its proposal.

Mr. MOSHER. What criteria do you use to determine that a university exhibits the promise of excellence? Are these criteria largely subjective? How do you measure one State university against another State university neither of which has any great reputation? How do you determine which has more promise of excellence than the other?

Mr. KEPPEL. My understanding is that the graduate school or the institution submits a 5-year plan of how it wishes to develop department by department emphasizing those departments which in its judgment, humanities, social sciences, or sciences, are at the point where more graduate fellowships would help them to move. Now, these institutional proposals, include departmental statements by special fields. These are reviewed in two ways. The criterion I think inevitably is to a degree subjective, sir; it is based on the judgment of peers—that is, we ask reviewers to look over these documents in the academic specialty first. It is secondly reviewed as an institutional whole by the advisory committee whose membership I will put in the record, sir. So you get, as I understand it, both, a subjective estimate department by department and also probably an institutional estimate done by the overall advisory committee which adds up the departmental estimates, which is even more subjective, perhaps, but at least it is based on judgment of academic peers at the bottom of the judgment process.

Mr. MOSHER. At best, it must be a very difficult business?

Mr. KEPPEL. Oh, it is horrible.

Mr. MOSHER. Since your funds are limited, at best there must be some inequities resulting where you throw out one university and accept another which is in reality pretty much the same?

Mr. KEPPEL. Numerically, sir, here is what happened for the 3,000 size program: We had 150-odd institutional applications and only 44 were funded, and my correspondence has not been uninteresting.

Mr. MOSHER. In fact, I participated in some of it.

Mr. KEPPEL. I thought I would put that as delicately as I could. It will be very clearly different when we move from 3,000 to 6,000 where a much higher proportion can be funded. It is inevitably I suppose that way, sir. I just don't know how you can put numbers on some of these judgments. There is a consensus reached. It is astonishing how much it is reached on many of the departmental judgments and institutional judgments. Perhaps, Mr. Valien, you want to add to this?

Mr. VALIEN. I would like to say in terms of the objective information which we require, we attempt to get the listing of the faculty, frequently their contribution to the academic world in terms of research and in terms of production of students. We get also the resources of the university in terms of its endowment, in terms of its appropriation from the State legislature and from private foundations, its resources from other agencies of the Government who are also put into this equation, and the trend in its graduate enrollment. The trend in its doctorate enrollment is also studied to see if it is actually going up. We ask also the number of qualified applicants whom they had to turn down because of lack of adequate faculty or facilities. These are some of the objective emphasis which also go into the situation. Then, also, there is at least a limited period of experience which we have had. Some universities have not been able to use all the fellowships we have given them. That I think we would look at with a great deal of concern for applications of an increased number.

Mr. KEPPEL. In figures 4, 5, and 6 (pp. 302–304), we show the present state of distribution of this program. By academic fields, you may want to note, Mr. Chairman, and this statistic has been fairly steady for the last few years, 60 percent of these fellowships are in the humanities, education, and social sciences, and 40 percent in biological physical, and engineering. It has been holding at about that rate in recent years. And then a State-by-State distribution running back to the very first year of the NDEA program is shown in figure 5 (p. 303), starting with 1,000 the first year and then 1,500 and now 3,000 and showing the number of fellowships by State. And finally a kind of geographic breakdown on 9c (fig. 6, p. 304).

I think the committee may be more interested in the footnote than in any testimony. The footnote shows the relative distribution of these Ph. D. programs by regions, showing that relatively speaking we have very deliberately, because of the nature of the act put a higher proportion in, for example, the Southeast. A higher proportion of fellowships have gone there than the institutions in that part of the country contribute to the total college teacher population. Clearly the intent of the Congress was to strengthen those programs in the country or to help those which could establish new or expanded Ph. D. programs.

Mr. VALIEN. May I say that 20 percent of the total fellowships of 11,500 have gone to the Southeast, for example. That is the highest proportion of any region.

Mr. KEPPEL. This we understood to be the intent of Congress in this particular program. As you can see, sir, there is a breakdown as to percentages and numbers, and so forth, on 9c.

To go back, Mr. Chairman, to your earlier question, as to how this relation with NSF is carried out, on the top of page 10, I point out it has been informal rather than official. I think perhaps the word "statutory" would be better than the word "official" because it is official enough whenever we have a conference Mr. Riecken or somebody is automatically asked on the policy questions.

One way, of course, of doing this, sir, I am not sure that Dr. Haworth altogether appreciates this, is to go and raid his staff, so you have men on our staff who know the NSF procedures. And the informal meetings are of the sort we mentioned before. In the middle of page 10, sir, the final area of mutual responsibility arises from several pieces of legislation which authorize the Office of Education to conduct what is called "research in education." I list five of them—these are special acts of Congress, Mr. Chairman, special instructions, special authorizations—handicapped children, modern foreign languages, new educational media, adult and vocational education, where I think Mr. Brown will recall that in the Vocational Act 10 percent of the funds are set aside for research and development in the new Vocational Technical Education Act, so as the total appropriations of Congress go up in this act, the amount of such research automatically rises with it. Last year it was at the rate of $11½ million, this year $17 million, I think.

Finally, No. 5 is the so-called cooperative research program, the one that is now 10 years old, starting then at a million dollars, and now we seek before the Congress $25 million in the current fiscal year.

The program, as I suggest at the bottom of page 10 and the top of 11, has grown particularly in the last few years with 3,000 separate contracts and grants for research and institution and they have gone to every State of the Union. This cooperative research program is by far the largest, the most extensive, and covers the widest ground by statutory authorization of any of these research programs and is the one with which NSF has had the most relation, sir.

On the middle of page 11 I have set in my formal testimony the four criteria that are used by the reviewing process, significance, the research design, the competence of the staff and facilities, and let us call it the economic efficiency of the proposed project. We have the usual system, that I am sure the committee is familiar with, of field reviewers if it gets to a certain point. There is a research advisory council which we appoint, whose membership I would like to enter into the record, if I may, who look at the final proposals. We also have the names, sir, of the various members of the panels.

Mr. DADDARIO. I would appreciate in each case that you refer to a committee you would supply its membership, and that includes the ad hoc committees.

Mr. KEPPEL. Yes, sir.

(The information requested is as shown below. In addition, the membership of other advisory committees are contained in a publication of the Office of Education entitled "Public Advisory Committees," a copy of which may be found in the committee files.)

COOPERATIVE RESEARCH PROGRAM

RESEARCH ADVISORY COUNCIL

Dr. Fred C. Cole (chemical), president, Washington and Lee University, Lexington, Va.

Dr. G. Franklin Edwards,[1] professor of sociology, Howard University, Washington, D.C.

Dr. Albert H. Marckwardt, professor of English, Princeton University, Princeton, N.J.

Dr. Patrick Suppes, professor of philosophy, Stanford University, Stanford, Calif.

[1] Terminated June 30, 1965.

Vacant position.
Dr. Samuel M. Brownell,[1] superintendent of schools, Detroit, Mich.
Dr. Jacob Getzels, professor of psychology, University of Chicago, Chicago, Ill.
Dr. Thomas R. McConnell,[1] professor of higher education, University of California, Berkeley, Calif.
Dr. Alan T. Waterman, 5306 Carvel Road, Westmoreland Hills, Washington, D.C.

AD HOC BASIC READING RESEARCH PANEL

Dr. Harry Levin, Project Literacy, Cornell University, 320 Wait Avenue, Ithaca, N.Y. (chairman).
Dr. Jeanne Chall, Department of Psychology, City College of New York, New York, N.Y.
Dr. Theodore Clymer, College of Education, University of Minnesota, Minneapolis, Minn.
A. L. Danis, Department of English, Illinois Institute of Technology, Chicago, Ill.
Dr. Eugene Long, Department of Psychology, University of North Carolina, Chapel Hill, N.C.
Dr. Patrick Suppes, professor of philosophy, Stanford University, Stanford, Calif.
Vacant position.
Vacant position.

ARTS AND HUMANITIES PANEL

Dr. Allen Britton, School of Music, University of Michigan, Ann Arbor, Mich.
Dr. Gerald Else, Department of Classical Studies, University of Michigan, Ann Arbor, Mich.
Vacant position.
Vacant position.
Dr. Jerome Hauseman, School of Art, Ohio State University, Columbus, Ohio.
Dr. Maurice Mandelbaum, Department of Philosophy, Johns Hopkins University, Baltimore, Md.
Dr. Edgar Richardson, director, Henry Francis duPont Winterthur Museum, Winterthur, Del.
Vacant position.

CURRICULUM IMPROVEMENT PANEL

Dr. Lawrence Cremin,[2] Department of Social and Philosophical Foundations, Teachers College Columbia University, New York, N.Y.
Dr. Edward Mattil, Art Education Department, Pennsylvania State University, University Park, Pa.
Dr. Melvin M. Tumin, Department of Sociology, Green Hall, Princeton University, Princeton, N.J.
Vacant position.
Vacant position.
Dr. Ole Sand, director of instruction projects, National Education Association, 1201 16th Street NW., Washington, D.C.
Dr. Charles A. Whitmer, head, course content improvement program, National Science Foundation, Washington, D.C.
Vacant position.
Vacant position.

DEMONSTRATION PANEL

Dr. Henry M. Brickell, assistant superintendent, Manhasset Public Schools, Manhasset, N.Y.
Dr. Nathaniel Gage, Department of Psychology, Stanford University, Stanford, Calif.
Dr. Robert Glaser (chairman), 205B Mineral Industries Building, University of Pittsburgh, Pittsburgh, Pa.
Dr. J. Thomas Hastings, director, Center for Instructional Research and Curriculum Evaluation, University of Illinois, Urbana, Ill.
Dr. Russell Kropp, director, Institute of Human Learning, Florida State University, Tallahassee, Fla.

---

[1] Terminated June 30, 1965.
[2] Dr. Cremin is on leave from the university and his address is: Center for Advanced Study in Behavioral Sciences, 202 Junipero Serra Boulevard, Stanford, Calif.

Dr. Harold Martin, director of general education, Harvard University, Cambridge, Mass.
Dr. Hollis A. Moore, Jr., W. K. Kellogg Foundation, 250 Champion Street, Battle Creek, Mich.
Dr. Wade Robinson, Associate Director, Office of Economic Opportunity, Brown Building, 19th and M Streets, NW., Washington, D.C.
Dr. Robert Travers, Department of Psychology, University of Utah, Salt Lake City, Utah.
Dr. Talman Van Arsdale, Jr., president, Bradley University, Peoria, Ill.

English Panel

Dr. John Carroll, Graduate School of Education, Harvard University, Cambridge, Mass. (chairman).
Dr. Robert Pooley, professor of English, University of Wisconsin, Madison, Wis.
Dr. Theodore Clymer, professor of education, University of Minnesota, Minneapolis, Minn.
Vacant position.
Vacant position.

Environment Panel

Dr. Roald Campbell, Graduate School of Education, University of Chicago, Chicago, Ill.
Dr. Theodore Newcomb,[1] Department of Social Psychology, University of Michigan, Ann Arbor, Mich.
Dr. William Sewell, Department of Sociology, University of Wisconsin, Madison, Wis.
Dr. Richard Snyder, Department of Political Science, Northwestern University, Evanston, Ill.
Dr. Anthony Wallace, Department of Anthropology, University of Pennsylvania, Philadelphia, Pa. (chairman).

Educational Processes Panel

Dr. J. Stanley Ahmann, head, Department of Psychology, Colorado State University, Fort Collins, Colo. (chairman).
Dr. Philip H. DuBois, professor of psychology, Washington University, St. Louis, Mo.
Dr. Daniel E. Griffiths, associate dean, School of Education, New York University, New York, N.Y.
Dr. Miriam L. Goldberg, associate professor of psychology and education, Horace-Mann Lincoln Institute of School Experimentation, Teachers College, Columbia University, New York, N.Y.
Hon. Byron W. Hansford, commissioner of education, State Department of Education, Denver, Colo.
Dr. Thomas Jordan, professor of education, Southern Illinois University, Carbondale, Ill.

Psychological Processes Panel

Dr. Kathryn Blake, College of Education, University of Georgia, Athens, Ga.
Dr. Royal Embree (chairman), professor of educational psychology, University of Texas, Austin, Tex.
Vacant position.
Dr. David G. Ryans, director, Bureau of Educational Research, University of Hawaii, Honolulu, Hawaii.
Dr. Robert L. Thorndike, professor of psychology, Teachers College, Columbia University, New York, N.Y.

Research and Development Centers Panel

Dr. Benjamin Bloom, Department of Education,[2] University of Chicago, Chicago, Ill.
Dr. Alan Pifer, vice president, Carnegie Corp., New York, N.Y.

---

[1] Temporary address for Dr. Newcomb: Western Behavioral Sciences Institute, 1121 Torrey Pines Rd., La Jolla, Calif.
[2] Terminated June 30, 1965.

Dr. Ralph Tyler, director, Center for Advanced Study in the Behavioral Sciences, 202 Junipero Serra Boulevard, Stanford, Calif. (chairman).
Vacant position.
Vacant position.

AD HOC INTERAGENCY COMMITTEE

PARTICIPANTS

For the National Science Foundation:
- Dr. Henry W. Riecken, Associate Director, Education.
- Dr. Thomas W. Fontaine, Director, Division of Graduate Education Support.
- Dr. Howard E. Page, Director, Division of Institutional Programs.

For the National Institutes of Health:
- Dr. John F. Sherman, Associate Director for Extramural Programs, OD.
- Dr. Eugene A. Confrey, Chief, Division of Research Grants.
- Mr. Joseph S. Murtaugh, Chief, Office of Program Planning, OD.

For the National Aeronautics and Space Administration:
- Dr. Thomas L. K. Smull, Director, Office of Grants and Research Contracts.

For the Atomic Energy Commission:
- Dr. Russell S. Poor, Director, Division of Nuclear Education and Training.
- Mr. George Courtney, Assistant to the Director for Plans and Programs.

For the Office of Education:
- Francis Keppel, U.S. Commissioner of Education.
- Peter P. Muirhead, Associate Commissioner for Higher Education.
- Dr. John W. Ashton, Director, Division of Graduate Programs.
- Dr. Kenneth W. Mildenberger, Director, Division of College and University Assistance.
- Dr. Alan D. Ferguson, Consultant, Program Support Branch.

Mr. KEPPEL. Generally speaking, the burden of identifying the areas of need for research and development rests with the individuals and the institutions that request the support from the Office of Education. Through this combination of individual and independent initiative and these reviewing procedures, research has been supported within many fields within education. That is we have had experimental surveys, correlation, the usual range that you would expect, sir. Among the variety of topics that are covered by these programs are mental retardation, child development, aptitudes and abilities. One study that has been of interest to the committee is one that focused upon a talented group of young high school graduates, beginning in 1960 and following them through college, to see where the loss of talent takes place. This may give the committee some background information about future leaders in the arts and sciences and so forth.

I list other types of areas on which we have invested funds for research. One of the major aspects of this program is the curriculum improvement program, and here we come closer still to the relation with NSF. In this area a project may deal with, let's say, a curriculum or a particular course or subject or any one of these. It may cover any subject field at one or more grade levels of education from preschool right through higher and adult education under the statute. The program of the Office represents an effort to approach this area as an integrated whole. It is obviously conscious of the need to relate its curriculum development projects to other efforts in the field both up and down the grade levels and across the related academic disciplines. For these reasons the Office tries to identify and then to stimulate projects to fill gaps which may be created by the development of specialized courses or curriculums or to provide alternatives to already existing curriculum improvement efforts.

May I emphasize that, to provide alternatives. My point is that the basic choice of curriculum now in this country rests with the local school board or the college, and in my judgment should. If the local school board or college is to have a real choice, to have a real decision to make about its content, its curriculum content, in our judgment there is a lot to be said for having several types of proposed new ideas, new curriculums available to them to make a choice. On that point the choice becomes real. This is in our judgment a way to be sure of the genuineness of school board and local school authority control over the curriculums. This is a policy which we have often discussed with the National Science Foundation. They are in a completely agreed upon joint policy.

Mr. DADDARIO. Do you bring this up to show the need of having within NSF and or within the Office of Education various alternatives rather than two agencies which might have different roads to travel?

Mr. KEPPEL. The second, sir, within each it seems to me. Obviously here, this curriculum development area, is an area in which there could be overlapping because of the broad authority given to the research program. In point of fact, we now are jointly financing with NSF. I think it is six programs in mathematics and science. Most of the curriculum development programs in mathematics and science are financed by NSF as is only reasonable and proper.

Mr. DADDARIO. If NSF was not involved in curriculum development, you would find that there would be alternatives as you probed into the subject matter yourself?

Mr. KEPPEL. Yes, sir.

Mr. DADDARIO. Your recommendation is that these alternatives are important and ought to be made available to the local school boards and the colleges as a guide, but only as a guide?

Mr. KEPPEL. That is much better stated than I stated it. That is exactly right. I think it is a very important public policy here that we are discussing here. The NSF itself established this policy it is fair to say before the Office of Education entered the curriculum development movement. We agreed with it, admired it and followed it.

Mr. DADDARIO. I bring it up because the point has been raised from time to time that one of the values of curriculum improvement comes from the fact that NSF and the Office of Education are separate agencies and as a result it opens up an opportunity for alternatives. You have added to this by showing that within each agency there ought to be no one approach, there should be a proliferation of approach rather than a condensation.

Mr. KEPPEL. Yes, sir; I agree.

Mr. GIDEONSE. We have two major projects, a series of projects actually. We call them Project English and Project Social Studies, but we deliberately went out and sought multiple approaches to curriculums in these areas. NSF has done the same thing in biology and chemistry. They deliberately set out doing three approaches to biology and two in chemistry so there would be alternative choices to the schools.

Mr. KEPPEL. I think, sir, it might be useful for the record if I were to say this, sir, with regard to these curriculum projects. There seems to be two reasons why the alternative or even competing approaches in English or history or something else are desired. No. 1, this

is the way to assure genuine decentralization, genuine choice at a local level rather than what could be an imposition of Washington's views. But, second, sir, we are a very long way in most of these subject fields from having the real confidence that such and such is the most efficient way to teach arithmetic or the most efficient way to teach English or a language.

Mr. GIDEONSE. I think we are more confident that there are many, many different ways to teach English and mathematics and social studies, and we ought to leave the choice as to which one to follow in a given case to the people who are really closest to the children or the teachers and the particular competencies or problems that a community may have.

Mr. DAVIS. I am really familiar with the education picture in only one State of the Union, and that is my native State of Georgia. Within the last decade the State has acquired the power to control the curriculum of a county or a city school board. However, it has exercised it only in the most gingerly way, and it may never exercise it very much. I would like to know if that is true in other States, or do you find that school districts are generally autonomous in this respect?

Mr. KEPPEL. There is a wide variation, sir, across the country. For example, by statute I would guess that the State of New York probably has potentially in the legal sense the greatest direct control over the curriculum. I am not sure of this, but I think that is true; whereas, you would find that some other State has in effect none. You get a variation here. In some cases the State legislatures have themselves, in effect, become curriculum committees and have instructed the schools to teach some subjects at a particular grade level, or a particular topic. Usually, however, such actions of the State legislature by statute are limited to a particular subject.

Mr. DAVIS. Such as the history of the State?

Mr. KEPPEL. Yes. In California recently the State legislature has instructed the schools to teach foreign languages when the children are young.

Mr. BROWN. The sixth grade. They are importing teachers from all over the country and outside the country.

Mr. KEPPEL. I have heard some complaints about that, Mr. Brown. You do get a varied picture. In most cases I think I would say that the State departments of education if they had the power, and this would be true in New York, have deliberately encouraged local judgment as a matter of policy. I would have to make a few exceptions perhaps, but the exceptions would be really exceptions and the majority would be acting I take it rather than the way that Mr. Purcell and his colleagues are in Georgia.

Mr. DAVIS. Thank you.

Mr. KEPPEL. At the bottom of page 12, Mr. Chairman, I refer to some of the methods we have been using for coordinating practices between the National Science Foundation and our office.

Cooperation has been institutionalized by the appointment of an NSF staff member to the OE Curriculum Improvement Review Panel since the initiation of the curriculum improvement program. NSF and OE staff members have conducted joint site visits to investigate

the research potential of proposed project locations. The Office and NSF jointly review and fund proposals which relate to both agencies.

These, then, are the major areas of mutual responsibility: the construction of graduate facilities in institutions of higher education; fellowships for future college teachers; teacher institute programs; and certain kinds of research in education. I have tried to demonstrate the effectiveness and importance of the coordination that we have been able to achieve between the two agencies. Your invitation to testify also requested that I address myself to a discussion of areas where it might be desirable to consider in greater detail the nature of the relationship between NSF and OE programs.

In addition to some differences already discussed, questions ought to be raised about the efforts to improve school curriculums through the support of course content improvement projects under NSF and curriculum improvement projects under Cooperative Research in OE. As both agencies continue to undertake this kind of activity in different disciplines, it will be necessary we suspect to oversee cooperatively activities along the whole range of curriculum improvement to insure the preservation of pluralistic, diverse, and multiple approaches to curriculum and the enhancement of the spirit of experimentation at the local level, which to NSF and the Office of Education seems very desirable. Increasing attention will have to be paid to the problem of how schools will "mix and match," if you will, the various courses being developed and indeed whether or not this is possible at all. Coordination of Federal activities in support of curriculum improvement is necessary to assure the continued existence of alternative choices for local policy planners without at the same time fomenting curricular anarchy in the Nation's schools.

A second question, closely related to the last one, involves the relationships between NSF and OE institute programs and between both and the curriculum improvement programs. It is well established that to be truly effective teachers must be trained in the use as well as renewed intellectually with regard to the content of the new curriculum materials. Both NSF and OE now operate major institute programs. As curriculum improvement efforts become more sophisticated, better efforts will have to be made to insure that teachers are able to adopt varieties of new practices, and adapt their teaching to fit the needs of children moving from school to school and program to program.

The Office of Education is relatively new at this enterprise in all fields except one. In modern foreign language it has had quite a lot of experience, but moving out of that field into English and history that we are now authorized in, we have had less experience in this than the National Science Foundation has had. Relatively little attention has been paid to this need in its larger ramifications, and although some NSF institutes have paid attention to the problems of teaching the new concept, the NDEA institutes have perhaps more consistently concerned themselves with the teaching of the subject while continuing to place major emphasis on the subject matter itself.

I am very grateful for your kindness in listening.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. I wanted to make an inquiry about some of the subject areas in this cooperative research activity. You have listed a number of items on page 12, which I don't think is an exhaustive

list. Have you engaged in any research projects involving some of the newer technology in educational TV? Have you been involved in some of these experiments where they have, for example in the Midwest, had the airborne TV or even satellite TV communication and its applications to various situations? Could this be funded under your cooperative research program?

Mr. IANNI. Actually we have a special program for that, the new educational media program which is also listed here. This specifically is designed to support research and demonstration in new techniques of education primarily using some of these new media. For example, we have supported some of the airborne television experimentation. We have done a considerable amount there in studying new ways of programing materials through the use of teaching machines and other devices of this sort, some of which has come along fairly well. For example, we have been experimenting with the development of new techniques for teaching the blind, and we have come up with a method that is actually four times faster than braille. Another technique which we have been experimenting with is teaching mentally retarded youngsters by the use of teaching machines and program devices. Here we have increased six times their ability to learn new words by using these techniques. I think it is fair to say that the whole idea of programing and computer instruction is very new and a great deal has to be done in the future on this.

Mr. BROWN. I am questioning the research, not the applicability of it. I am wondering whether the Office of Education is concerned with funding research or whether it is being funded in some other areas. For example, within the last few months it has come to my attention that a study in satellite education or educational TV used in satellites has gone to the AID because it has applications obviously in education of large underdeveloped areas. I would think that the development of programs in this area would have been tested perhaps in the United States, or that some research had been done in an area of this sort perhaps by the Office of Education. I recognize in a field which is changing as rapidly as this, it perhaps may not be desirable to try and put it into large-scale operation, but certainly there should be research on it.

Mr. IANNI. I would say this has been our principal approach. It is still highly experimental. We would be glad to supply for you a list of projects in this area to give you some idea of what is going on.

Mr. MILLER. Will the gentleman yield?

Mr. BROWN. Yes.

Mr. MILLER. What reports or results do you get from the system presently being used in Samoa?

Mr. IANNI. The new television technique there?

Mr. MILLER. Yes.

Mr. IANNI. Our experience has been that it is quite successful there. It is successful for some very specialized reasons. One is you have a very large area to cover, which is where educational TV tends to be most successful, and, second, that the level of education is low enough that you can use techniques for teaching reading, for example, and language instruction. Our experience has been that it is quite successful, and it could be used elsewhere.

Mr. MILLER. I visited Samoa with some members of the committee last year. We saw it being put into effect. I was struck with these youngsters learning the language. When we walked in behind them they didn't pay any attention to us. They were repeating after this voice, saying, "Yes," and they say "Yes." Since then I have seen an article that this system was more or less developed in Australia; is that correct?

Mr. IANNI. Actually in Australia, and I think ethnic chauvinism would lead me to also point out that it was developed in Italy. They have used it quite extensively there, particularly teaching in southern Italy with great success.

Mr. BROWN. Would you supply for the committee some information with regard to your research in these areas of program instruction, educational TV, satellite communication?

Mr. IANNI. Yes.

(In response to the above request, Mr. Keppel has submitted the following reports of the Office of Education, copies of which may be found in the committee files: "Cooperative Research Projects, a Seven-year Summary, July 1, 1956–June 30, 1963," OE12018; "Cooperative Research Projects Approved in Fiscal Year 1964," dated June 1964; and "Projects Initiated Under Title VII, Pt. A, National Defense Education Act, September 2, 1958–April 30, 1964," OE–34013–64.)

Mr. BROWN. I have a comment with regard to another area, the allocation of fellowships by academic fields. We have been questioning other witnesses in regard to the breakdown between the physical and biological sciences, and the social sciences. I notice in your table on page 9–A that the emphasis as far as your office is concerned is largely with the humanities and the social sciences—60 percent of the fellowships going to that area. This is a matter in which I think we need close coordination between the Office of Education and the National Science Foundation in order to get the proper balance throughout the various fields of activity.

Mr. KEPPEL. May I comment on this, Mr. Brown?

Mr. BROWN. Yes.

Mr. KEPPEL. To emphasize again, the intent of Congress with the NDEA Ph. D. fellowship program was aimed to increase the number of college teachers. The NSF's responsibilities are, of course, much broader than that for science as a whole. If you take a look at the academic role of higher education in general, something like 60–40 or 65–35 in there is the balance that exists between the number of college teachers in the humanities and the social sciences on the one hand, and the sciences on the other. We are, therefore, trying to keep the intent of Congress in mind in providing new people going into college teaching.

One other fact, Mr. Brown, might be relevant here. I don't have at my fingertips the statistics of the number of Ph. D.'s in the physical sciences, in the social sciences, and in the humanities who actually enter the academic world, but roughly speaking, because of the demands on scientists in the public section, you have a much smaller percentage entering college teaching. What we do is to ask those who take part in these programs to demonstrate intent to enter teaching. On the basis of what is admittedly inadequate evidence, Mr. Chairman, because this program only started in 1958—1959 really—

as you know, in theory you get a Ph. D. in 3 years; in fact, you are lucky if you get it in 6, so that we don't really have much evidence. You have to add 5 or 6 to 1959 and we get to where we are now, the holding power, which is my word for the intent of Congress to get into teaching, is well ahead of the average in all fields, humanities, of these NDEA fellows. Eighty percent are entering college. They show a difference of the intent of Congress between NSF on the one side and NDEA on the other.

Mr. DADDARIO. Do you have any questions, Mr. Miller?

Mr. MILLER. No. I am sorry I couldn't get here earlier because I am very much interested in what Dr. Keppel has to say. NASA is undertaking a fellowship program and we are not tying the students down by requiring that they go to work with NASA. We are trying to perhaps replace in the reservoir the people whom we drew out of it. How, as an educator, do you look at a program of this kind?

Mr. KEPPEL. I have talked a good deal with Dr. Simpson, who is leaving NASA to go to Georgia by the way, sir, and with Frank Hanson, who is perhaps more directly in charge of this. What NASA is doing makes a lot of sense to me. What I understand they are trying to do is to strengthen the infrastructure in those scientific areas which relate to NASA in a broad sense which would include from biology through to physics. In developing our program, Mr. Chairman, at the first basic conference for this expanded NDEA, Dr. Hanson was one of the members of the group who helped to bring this new program in. I think George Simpson reviewed it later. It makes sense to me, sir, and my guess is it will do exactly what Mr. Webb hopes it will do—namely, strengthen the overall space program which he knows very well will have to be strengthened in the university as part of their regular breath of life, as well as increase the numbers of people that NASA may need. I may say, Mr. Daddario, relations with the space agency are made infinitely simpler by the fact we are in the same building. All we have to do is go up a couple of floors.

Mr. MILLER. I think that is very fine that you should be in the same building.

Mr. KEPPEL. In view of our expansion, I sometimes think Mr. Webb is a little nervous, but not that nervous.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Mr. Keppel, I would like to thank you for the statistical detail in your statement. Following up on what Mr. Brown was asking, if you put all the various agencies and fellowship programs together, are we balancing the need and the supply in both the social sciences and the physical sciences for teachers? Are we meeting the need everywhere?

Mr. KEPPEL. I think I would have to say "No, sir"; that is, the rate of growth of higher education, particularly with respect to this generation that is just becoming 18 and 19 years of age is so dramatic that the colleges are having a tough time getting the quality staff they need. Now to break it down field by field, we do have some data on this, we have been making some analyses which we would be glad to furnish for the record if requested. Let me make just one general statement, Mr. Conable; may I? Those of us in my kind of work have been very worried for the last 10 years, roughly, at one statistic. What percentage of those taking full-time college teaching positions for the

first time have a Ph. D.? As you go back about a decade, I may be a little wrong in detail—if the chairman would forgive me, I would like to correct the record—the percentage of those entering colleges for the first time with a Ph. D. kept going down, down; we were going into the 30 percent and down in the twenties. I wouldn't say for a moment, sir, being my father's son, that it is a necessary instrument to get into Heaven, because he never had one and managed to make a career out of it, but, in fact, it is an index of the lack of supply of college teachers. Last year, for the first time, the percentage of men with Ph. D.'s entering college teaching for the first time, started going up. This is the first sort of hopeful sign. But it is very clear that there are particular fields in which the shortage is acute. Again to take a figure out of my memory, I think a year ago we had something like one-seventeenth of a new Ph. D. in mathematics per institution in higher education in the United States. The supply was that short.

Mr. CONABLE. If you had $100 million extra to put into graduate study, where would you put it? Would you put it all in the social sciences, or all in the physical sciences, or would you divide it in approximately the percentage in which it is being divided now considering all the agencies contributing to it?

Mr. KEPPEL. I won't say that this 60–40 we are using is right, but it is in the right ball park, sir.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have a series of questions. Has our next witness arrived yet?

Mr. DADDARIO. Not as yet.

Mr. VIVIAN. A number of these questions will be connected, Mr. Keppel, with, as you point out, the rapid increase in new students. In fact I am startled every time I see those new statistics, and as I watch my own teenagers grow, I can understand why. They are phased in the curve long before we raise the revenue from their own efforts. We are building a new educational system. Certainly the change in the last 10 years is a totally new educational system. I think your research in education is one of the most fascinating parts of the whole story. I see it permeating into my own community. In this process, the respective roles of the Office of Education, NASA, NIH, and all the other agencies are becoming in my mind confused. I think it represents, in part, the fact that you are slowly shifting from a role of small participation, percentagewise, a participation which may be significant in a policy at a research level but not at a funding level to a situation which is becoming at least at the grade level a large involvement. It is no longer a policy of dearth; it is a policy of almost total support. With this, I think, the policy situation does have to change. Now, in terms of the total amount of funds expended, we have had some figures on science education as such and the involvement of the National Science Foundation. Do you have anything on the total amount of support provided by the Federal agencies, and the total support of science education in the United States?

Mr. KEPPEL. I don't know that the report that I have in my memory, Mr. Vivian, at this moment breaks it down quite that way. We have

gone through a summary; it is part of an interagency committee that was established, and we have been getting the raw data up, which I would like to enter into the record, if I may, sir.

This shows how the overall Federal funds are going. Let me give you an example of why I am not quite sure how to break down the figure. There is a figure in there of roughly $1 billion of what might be called vocational and technical education in the military establishment, I think that is roughly a billion. I don't quite know how to categorize that. Some of it might be reasonably called applied science and some of it perhaps should not be. I remember that particular figure as one. Perhaps we could enter this most usefully in the record, and I would be most delighted officially or personally to try to break it down further to get to the figure that your committee has in mind.

Mr. DADDARIO. It would be most helpful if you would.

(The information requested is as follows:)

FEDERAL FUNDS FOR EDUCATION AND TRAINING AND FOR SUPPORT OF ACADEMIC SCIENCE, FISCAL YEARS 1965 AND 1966

(U.S. Department of Health, Education, and Welfare, Office of Education, Office of Federal Education Activities, Federal Education Programs Branch, February 4, 1965)

Federal funds for education, fiscal years 1965 and 1966

[In thousands of dollars]

Type of support and academic level	Estimated obligations	
	1965	1966
Total	6,328,907	8,711,131
Elementary-secondary education	707,376	1,947,386
Support of local schools	609,205	1,631,906
Overseas schools	86,000	90,000
Supporting services	7,300	219,750
Other	4,871	5,730
Higher education	3,392,829	4,025,068

Federal funds for education, fiscal years 1965 and 1966 [1]—Continued

[In thousands of dollars]

Program by type of support and academic level	Estimated obligations	
	1965	1966
General adult education	89,513	115,741
Civil defense adult education, OE	4,006	4,006
Proposed urban community extension, OE		25,000
Agricultural extension service, Agriculture	85,107	86,335
Science education, NSF	400	400
Other education programs	170,508	185,246
Administration and services, OE and NSF [10]	53,101	58,830
Library services [11]	103,665	113,354
Educational television grants, OE	13,742	13,062

[1] Estimates from United States and agency budget documents. R. & D. estimates from National Science Foundation. Amounts for education estimated from larger budget entries in some cases. Excludes international education activities (see attachment I), school lunch program, and value of donated surplus property.
[2] Vocational education funds included in "Vocational-Technical and Adult Education" category.
[3] Estimated amount for schools from larger payments to States and counties.
[4] Includes estimated amount for schools from total Federal payment to District of Columbia and payments for Cuban refugee education.
[5] Estimate of Federal contributions for education from larger payments for support of public services.
[6] Includes R. & D. and curriculum development grants. R. & D. estimates from National Science Foundation.
[7] Program funds included in Manpower Development and Training Act entry.
[8] Estimated cost of military training programs exclusive of flight and recruit training. Higher education programs reported elsewhere.
[9] Preliminary estimate of amounts for education from community action, work experience, work training, and Job Corps programs. Part of the funds included support activities for preschool age children and basic adult education.
[10] Includes administrative costs, information services, and surveys and studies not reported in other categories.
[11] Includes grants to public libraries; operating expense of Library of Congress, Smithsonian Institution, National Library of Medicine, and National Agricultural Library; and depository library and catalogue and index activities of the Government Printing Office.

ATTACHMENT I

Federal funds for international education: Estimates for fiscal years 1965 and 1966 [1]

[In thousands of dollars]

Program	Estimated obligations	
	1965	1966
Total	381,688	399,253
Educational exchange program, State	53,224	54,964
Peace Corps, volunteer and project costs	84,775	100,600
American sponsored and dependent schools abroad, AID [2]	27,000	27,000
Participant training, AID [2]	35,000	35,000
Education projects, AID [2]	84,600	84,600
Educational assistance, USIA [2]	89	89
Research and development in foreign institutions [3]	97,000	97,000

[1] Data incomplete. The Federal Government also supports education through contributions to international organizations. Assistance to foreign students under regular student support programs of the various agencies are not included in the data above.
[2] Estimates based on 1963 and 1964 data, as available from published reports or responses to the Office of Education surveys of Federal education activities.
[3] Based on latest published data of the National Science Foundation.

Mr. VIVIAN. I would like to know the amount of total support for graduate education, which comes from all the Federal agencies. I mean to include Commerce——

Mr. KEPPEL. And Agriculture?

Mr. VIVIAN. Yes, all the agencies. There is also a State contribution, which is quite large in the United States as you go farther west. I would like this identified separately. Although it is a governmental support, it is not Federal.

Mr. KEPPEL. I have more confidence in the Federal data that we have rather than the State matching or the State contribution.

Mr. VIVIAN. I presume that is readily available?

Mr. KEPPEL. We certainly could get it.

(The information requested is as follows:)

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE, OFFICE OF EDUCATION

I. Education expenditures, fiscal year 1965

[In millions of dollars]

	Total	Public	Private
Elementary-secondary education [1]	26,900	23,500	3,400
Higher education [2]	12,100	6,900	5,200

[1] Includes adult education and community colleges financed through public elementary and secondary school systems. Federal funds include subsistence payments to individuals in training.

[2] Includes expenditures for subcollegiate departments of institutions of higher education. Federal funds include subsistence and other allowances to individuals in training.

Projected expenditures for education, in current dollars, total $39 billion for 1965. This includes $26.9 billion for elementary-secondary and $12.1 billion for higher education. Data are not available to report higher education expenditures by level (graduate, undergraduate).

II. *Federal funds for education, fiscal year 1965*[1]

[In millions of dollars]

Elementary-secondary education[2]	1,304
Higher education[3]	3,050
Research and development	1,134
Facilities and equipment	997
Graduate training	615
Undergraduate training	219
Agricultural extension	85

[1] Estimated obligations.
[2] Includes adult education and community colleges financed through public elementary and secondary school systems. Federal funds include subsistence payments to individuals in training.
[3] Includes expenditures for subcollegiate departments of institutions of higher education. Federal funds include subsistence and other allowances to individuals in training.

NOTE.—Federal funds for education total $6,329 million for fiscal year 1965. Amounts above exclude programs, such as Federal military training, which are not included with education expenditure data.

Mr. VIVIAN. I don't know how well you can do at the undergraduate level. I would presume the Federal participation in that level is much less than the graduate level.

Mr. KEPPEL. That is right. That is clearly the case.

Mr. VIVIAN. Then as you move to the elementary and secondary levels, I presume the percentage drops down again markedly, and I would appreciate some estimates of the expenditures at these various levels.

Mr. KEPPEL. The overall annual expenditures for elementary and secondary schools is of the order of $27 billion. When you add together the major Federal programs—and may I be an optimist and assume that the Congress will fund the new elementary and secondary act—we have $1.3 billion, to which one would add about three-quarters of a billion dollars more for national defense education, rehabilitation, and technical education. I think one would come out to a figure of roughly 2 billion. I am not including the Department of Agriculture free lunch program. We have something like one-tenth, one-twelfth——

Mr. VIVIAN. That is at the elementary school level?

Mr. KEPPEL. That is right.

Mr. VIVIAN. By the time you get to the college pre-graduate level, I suppose you should label it, your figure is 20 or 30 percent?

Mr. KEPPEL. I don't think it is that high.

Mr. VIVIAN. How about at the grade level?

Mr. KEPPEL. There it is much higher, very high in the sciences and medicine, much less in the humanities. On the other hand, the problem in keeping the books is difficult here. Let me give you an example. In the higher education facilities program that I mentioned earlier in my testimony, I think that 40 percent of the building money is going into libraries, which by the way I heartily agree with, and I suspect all of us would agree to. It is obviously a major contribution to the humanities and the social sciences but how you allocate it, I wouldn't know, sir.

Mr. VIVIAN. Relevant to these estimates, I believe it will turn out that the National Science Foundation's program is a relatively small factor to these determinations, as soon as you include the NASA and DOD funds. Do you have any comments as to whether that percentage

should be increased as a relative percentage? I will then ask you if you think the Office of Education percentage ought to be increased?

Mr. KEPPEL. It is a dangerous thing to ask an educator about more money for anything. The Office of Education percentage I am quite clear should be increased in certain areas. For example, we are before the Congress now, and I feel very strongly about it, with regard to the books that ought to go into these libraries. We have simply got to expand that area. I do not think, sir, at the present time, given our capabilities, the infrastructure and the like it would be wise radically to increase the number of Ph. D. fellows in the title IV of NDEA to which I have addressed myself. This may be a matter of administrative judgment not properly cast against the overall need. I think it is about as fast as we ought to go. As to NSF, those programs that I know best, those with curriculum development and the traineeships and the like——

Mr. VIVIAN. You deal most of the time in the House with the Labor and Education Committee, and you have been very ably presented before them. They have been generous in these last few years and I believe will be generous this year in the higher education program. The NSF budget goes through the Appropriations Committee and there is some tie with this committee. The NASA funds go through this committee. The NIH funds go to another committee as does the Department of Defense. In general, there are a number of congressional committees involved. As the head of the Office of Education, do you feel at any time you have a chance to present the total picture on the financing of education?

Mr. KEPPEL. I have felt no hesitation in presenting the overall story to the House Committee on Education and Labor, recognizing that some parts of it are presented to other committees. I have felt it is my point to try to give the needs and the priorities particularly, and it has been my judgment, sir, that the priorities in recent times are to the needs of disadvantaged children who were simply not getting an even break, to the obvious need of expanding the infrastructure for higher education.

Mr. VIVIAN. Right now your office is a part of the Department of Health, Education, and Welfare. There are many suggestions; there should be the Department of Education which would encompass the educational functions now in other groups. There is also a great deal of resistance. I am curious whether you have any comments you would like to make on that subject.

Mr. KEPPEL. May I make two comments? One of them: If a Government witness may say he isn't competent, the general question, I have thought a lot about. I think it is one of the phenomena of the last quarter century that the institution of education—the schools, the colleges, the universities—have become so enmeshed in the society, all aspects of the society, if I can do it alphabetically from agriculture through science, that in order to accomplish the goals of the society it is necessary to use these institutions. For example, the space program has obviously brilliantly used the resources of the universities as well as the great research enterprise in the private sector, the same in agriculture, the same in other fields. The point I am trying to make, sir, is my own view would be that it would not be wise to attempt, in the

40 Government agencies I believe that use the schools or the colleges to accomplish their particular purpose in one way or another, to get all of those programs under one tent. These schools and colleges, as I say, over the past century, have been paid the greatest of all compliments. They are so useful everyone wants to use them. I am not sure that it is necessarily wise to run everything through one central place like my office. It will probably slow up the paperwork. I don't mean that reorganization is necessarily undesirable, it is probably desirable sometimes, and I would like to disqualify myself for obvious reasons as the witness on this. I don't think we should ever get to the point where the agencies, such as NASA, NSF, and the Agriculture Department, cannot have direct relations with these institutions in our society that are so necessary to carry out their purpose. If there is a little confusion in this, I enjoy it, Mr. Vivian.

Mr. VIVIAN. I anticipated you would say something against such an operation like that, but I wanted to see what it would be. I think I would rather defer from any further questions at this time.

Mr. DADDARIO. Thank you, Mr. Vivian.

Mr. Keppel, we will have a series of questions which I hope we might send to you.[1]

Mr. KEPPEL. Of course, sir.

Mr. DADDARIO. I want to thank both you and the gentlemen with you for a very informative morning. Before these hearings are over, we would like to sit down and talk with you some more about this.

Mr. KEPPEL. I would love to, sir.

Thank you, Mr. Chairman.

Mr. DADDARIO. Our next witness is Dr. Isador Rabi of Columbia University, who has had wide experience in relation to the international aspects of science support. We are pleased to have you here, Dr. Rabi. We understand you had some difficulty in flying down this morning.

STATEMENT OF DR. I. I. RABI, COLUMBIA UNIVERSITY

Dr. RABI. There were a lot of Shriners and so many private planes that we were about an hour late coming down.

Mr. DADDARIO. Would you proceed, please?

Dr. RABI. Sir, I haven't testified before a committee for a long, long time, so I am not quite sure of the procedure you wish. I have a very brief biographical sketch with me and a brief statement perhaps bearing on only one part of the subject. Do you want me to read the biography and statement?

Mr. DADDARIO. The biography need not be read. It will be entered into the record as a matter of course, Dr. Rabi. You may handle your statement either by reading it or by paraphrasing it in any way you like.

Dr. RABI. I will read it, sir, because it is just as good an introduction as any. It is a warming-up period for the questions which you may have.

Gentlemen, I thank you for giving me the opportunity to appear before you to express some views on the applications of science that would make stronger the bonds between our country and nations which are or have been allies and those which have been enemies as

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

well as those who may be considered by some to be our potential enemies.

Since science is universal in nature, it has an appeal to every community on the globe and is, therefore, the commonly accepted intellectual currency of our time. The diffusion of science and the interactions of scientists provide the means of strengthening already existing bonds between our country and others, as well as opening new avenues of communications with countries where such communication has become very difficult or nonexistent.

As an example, I cite you the important role which science has played in the past in opening lines of communication between the United States and the Soviet bloc. The First Conference on the Peaceful Uses of Atomic Energy which took place in Geneva in 1955 broke through the Iron Curtain. For the first time we were able to meet with a large number of important Soviet scientists and to begin a dialog which has resulted in an important lessening of tension between the United States and the Soviet bloc. The most dramatic and significant evidence of the importance of such connections is in the ratification of the test ban treaty.

Another activity which I would like to cite at this point was the proposal which I had the honor of making on behalf of the U.S. delegation at the General Conference of UNESCO in Florence in 1950, where the United States proposed the formation of the now famous laboratory known as CERN, this is a high-energy physics laboratory situated in Geneva, Switzerland. It is the counterpart to the Brookhaven National Laboratory which also is devoted in large part to high-energy physics. There has been a most fruitful collaboration between these two centers as well as friendly competition. CERN is an entirely European organization comprised of about 14 European countries, each of which contributes a proportionate share to the operating and capital budget. The total sum expended is not small. I believe that it has already grown to over $100 million. One point which gives me great satisfaction is that all of this was done without 1 cent of expense to the American taxpayer. It is my hope that the organization which runs CERN may be the forerunner, prototype, or example for greater European cohesion which has been such an important goal of American foreign policy. In contrast to the Common Market, England and most of the EFTA countries are partners in this enterprise.

One more example of the structuring and strengthening of the bonds between countries lies in the work of the NATO Science Committee of which I have been a U.S. member since its inception in 1958. Under this committee, there is a scholarship program which enables various scholars from NATO countries to study in other NATO countries. A research grant program enables scientists to set up projects in which the cooperation of two or more NATO countries are used, both to advance the subject and to promote better relations. Oceanography, particularly of European waters, is a case in point. This committee also supports a large number, something like 45 of this year, of summer institutes which are really advanced schools in a varied range of scientific and technical fields. The institutes have done a great deal for the diffusion of scientific knowledge in the NATO countries, as well as to bring scientists of these countries into close collaboration. This effort has helped to raise the level of Western science in the last few years

and has, I believe, given a greater sense of basic unity to the Atlantic alliance.

Many instances can be added to those I have cited to show the importance of science to international relations. The importance of science in our present and future relations with the other countries in this hemisphere, in the countries of Africa, and of Asia is clear, because science is central to their hopes and aspirations for the modernization required to raise their standard of living to one appropriate to this century. There are many instrumentalities which have been employed to further American policy in these various areas. The military departments and the National Institutes of Health have, through their contract and grant program, done very effective work both in Europe and elsewhere. The National Institutes of Health has made stable contributions and, of course, our great private foundations have pioneered in these efforts.

The National Academy of Sciences has been very effective in maintaining relations with scientists of other lands. The fact remains that we have no central office or organization which could be the flywheel to maintain an even level of effort in communication without great fluctuations which may be dependent on the nature of the military budgets. The National Science Foundation is doing a great deal for the improvement of scientific education in the United States on the secondary school level. These efforts arouse considerable interest, both at home and abroad. The scholarship and fellowship programs are also well known. It, therefore, seems to me that we should try to give the National Science Foundation more funds and a greater opportunity to expand its program and its influence in the international field, in cooperation with the Division of Science Affairs in the State Department.

Gentlemen, I have had for various reasons very little time to prepare these remarks, so it covers only a very small portion of what I might have to say or whatever experience I have had which might be useful to you. I would prefer, instead of going on ad lib, if it is all right with you, to answer questions.

Mr. DADDARIO. Mr. Chairman.

Mr. MILLER. Doctor, may I add to the list of these groups that have worked so well in this field the U.S. Mission for Peaceful Use of Outer Space that meets in Geneva. I think it has made a great contribution to understanding in the world, bringing about the things that you and I desire.

Dr. RABI. Yes, sir. I think that one can make the opening moves in a new relationship through the scientific community perhaps more readily than in any other way, and it is my hope that perhaps in the not too distant future you may make some moves in that direction with respect to mainland China.

Mr. MILLER. Mr. Chairman, in 1960, I had the privilege of being in Paris, Mr. Yeager was along, and we visited the NATO Scientific Committee and saw Mr. Rabi at his best in that committee, and I long remember this fine experience, Doctor.

Dr. RABI. Thank you very much. I might add recently I have begun to see indications of perhaps a warmer coperation to come through the actions of this committee with the French.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. A series of questions, if anyone would like to begin first.

Mr. DADDARIO. No; you go right ahead.

Mr. VIVIAN. In reference to the overall subject of international participation in science, I am quite interested in your remarks that there is no central office or organization to maintain a consistent or balanced policy and level of effort in communication with the foreign scientific communities. You comment on the Division of Science Affairs in the State Department. Does not this Department have a clearly defined function in this area?

Dr. RABI. I think it has, and it has been consistently disappointing in the sense that it has not worked too well for a number of reasons. It is a new graft onto the State Department, and a great deal depends upon the nature, the kind of man who is selected to head this Division and the Secretary of State. I have always pictured that relationship as one parallel, let's say, to the Special Assistant for Science and Technology to the President because, as President Eisenhower discovered, as soon as he had this special assistant, there were very few problems which came across his desk which didn't have a scientific aspect.

The working of this relationship depends a great deal on the people concerned. It has to be in real symbiosis. We have had excellent men in the State Department occupying the position of science advisory, but it has never clicked quite the same way for reasons which perhaps——

Mr. VIVIAN. Some days ago when Dr. Hornig was here, I inquired into the matter of his relationship into national scientific affairs, and I think he indicated that he had a significant responsibility for scientific affairs overseas as well as here, continentally. Would you construe the situation then as one in which the person in the State Department and Dr. Hornig represent the key personnel guiding the subject?

Dr. RABI. That would be the ideal, but, of course, if we are active in science in foreign affairs we need a much bigger staff, the programs have to be examined and evaluated, and neither the Office of Science Affairs in the State Department nor the Office of Science and Technology and the President's Science Advisory Committee have, and I think they should not have, that sort of staff. I would like to see it operate in conjunction with the National Science Foundation but not excluding other agencies which are active in the field. I would like to see some central agency which gathers the experience and the staff over a period of time and which is central, not exactly in coordinating but in operating through this field.

Mr. VIVIAN. In other words, you feel that the operating functions could be well handled at the NSF level whereas the policy guidance would have to come through the State Department?

Dr. RABI. The policy guidance will have to come from the President in various forms—through the State Department is certainly one. Defense has a strong interest and the Congress has a strong interest and the Atomic Energy Commission has a tremendous interest. They are all in this field. They all have representatives abroad, and they are all doing a very good job.

Mr. MILLER. Doctor, because the Science Advisory Committee and the Science Department in the State Department are comparatively new, some time is needed to get acceptance, and isn't this acceptance coming more and more within the Department? I know last year I was invited to go down and discuss the relation of Congress and science at the State Department Institute where they are teaching their new people. This, I think, was the first time that anyone had been invited down there to do this. I hope it will grow.

Mr. VIVIAN. I hope that it will, too, and when I see the excellent people that have gone overseas—I am certain that you know Dr. Piret, who is in Paris and who is coming back now for a year or two. They want him to go back and I don't mean him exclusively to exclude others.

Dr. RABI. Yes, sir. I think it will come. I think it is beginning to be realized more and more in the State Department that this is a responsibility. There have been serious difficulties because the chief man has been there usually at most 2 years. He is a man who comes in without any background in foreign affairs, and about the time he is beginning to have a feeling for the political side, which he has to have to advise the Secretary of State—he has got to turn this scientific material into something which is digestible to the Secretary, which means into the political aspect—by the time he has begun to learn to do this, his term is up and off he goes and there is a hunt for another man. The attachés to whom you refer, some have been very good in gathering information and so on, but the the actual policy guidance, where they might be effective, still has to be improved. They have two jobs. They have to advise the Ambassador and then they have to advise the people back home, and that has to be turned into the kind of information and advice which could be useful. I think we are learning it is new—it is brand new as far as we are concerned. I think we are learning.

Mr. VIVIAN. You indicated a desire for NSF to have a larger international role, which I certainly don't disagree with. That suggests by implication that you might like to see programs similar to those which NSF is now handling on a national scale extended in some way to an international scale, presumably with some U.S. financial participation. Can you outline your thoughts in this area, if you have any you would like to mention?

Dr. RABI. I think in this century, and in the foreseeable future, the prestige of a nation will depend very largely on its scientific strength and the scientific quality. I am talking now on the educational-intellectual scientific side and entirely apart from applications, entirely apart from military strength. These are not unconnected. But if the scientific standing of a country is high, its prestige is high. Its prestige is high, it seems to me, in a way which doesn't frighten people. It shows the beneficent, cultural side of science. I think this is a central and important aspect. The United States in the last 30 years has begun to reach a position of leadership, as the No. 1 scientific country, and I think it is very important to present this to the world in an active kind of way. Likewise, this country I think has done more than any other country in studying the problems of scientific education. I think we have the best universities, the best means in the world of educating a large fraction of the population, large

as those things go, in science and in technology. We have something new. This is not understood abroad because among the great qualities we have is this fantastic ability for self-criticism. Abroad they are likely to believe more of the bad things we say about ourselves than the obvious good things. People in France have complained to me:

You criticize your system so much that our people think they are better when actually they don't begin to be as good.

In this field where the National Science Foundation has pioneered and supported I think it can do a great deal abroad not by spending large sums but by making material available, by discrete use of propaganda. It would very greatly improve the image, I hate to use that word, of the United States. It is very important. Countries as people just don't like to follow strength alone. They want to follow a culture that they can really respect, not only because it is strong and rich. I think in our science we are unquestionably ahead of every other country, as we should be for our size and wealth. I think it should be clearly understood by the general public of those countries. It is understood by the scientists, of course. I think in this field the National Science Foundation can do a great deal as an operating agency through possibilities of fellowships, cooperative projects, visits, and things of that sort.

While I am talking about this I might add it came out very strongly in our committee to which Mr. Miller referred that the Air Force and the Navy and the Army have done wonderful work in Europe and are highly respected for their grants program and the way in which they supervise them and the quality of the work which was done under those programs.

Mr. VIVIAN. Do you think that those programs would be as well or better done under NSF sponsorship rather than military sponsorship?

Dr. RABI. One can't predict because so much depends upon the quality of personnel that is chosen, but I think, given the people, the same kind, it would be easier to do a better job.

Mr. VIVIAN. Let me restrict myself solely to their acceptance of the work rather than the administrative work, do you think they would prefer to see it handled by NSF rather than the military agencies?

Dr. RABI. You mean our customers?

Mr. VIVIAN. Yes.

Dr. RABI. I am sure they would. It is always a shock, due to the history of the European countries. In our country because of the war effort the scientific community formed a close relationship with the military, one of respect, whereas in Europe it is quite different. You will find very few European scientists who are not antimilitary. They have the old image of the military, and in some sense it is well founded.

Mr. DADDARIO. Their scientists do not share that feeling in working with some of the American military departments in these programs. They would just as soon work with a military agency provided the military agency allows them the flexibility that they would like to have, isn't that so?

Dr. RABI. I agree with you. The military have done so well that the original curse, so to speak, is altered, and they have done a very beautiful job in handling it, a very sensitive job.

Mr. DADDARIO. Following Mr. Vivian's questioning in this regard, if the programing and the funding could be expanded under an agency like the National Science Foundation, we would be ahead propagandawise as well as scientifically.

Dr. RABI. I agree, but, as I suggested, I also want to see the flywheel effect when you begin to have the fluctuations in military budgets—and I do hope sometime in the future if we get to a better world that the military budgets will go down drastically, but these other needs that we have in international science will not——

Mr. VIVIAN. Dr. Rabi, you mention in here the fact the changes in science over the last 10 years have had a significant effect on the relationship between the United States and Russia, the degree of communications between these two nations. I have seen this in my colleagues. The large number of trips which have been taken and the remarks and conversations which have been made very obviously have transcended the bounds of the Iron Curtain.

On the subject of international cooperation, I picked a very specific subject some months ago to encourage cooperation rather than the general words. I have suggested strongly to NASA and to other persons in the Government that the Voyager project which leads to the landing of a capsule on Mars some years hence might be a place for scientific cooperation. I believe that scientists throughout the globe feel that the exploration of Mars is of major scientific interest because of the possibilities for life on Mars. I have suggested that the landing which would be quite separate from the conveying vehicle, might, if possible, be designed by an international consortium as a means of spreading our interest in space science throughout the world. Do you have any comments on that type of approach?

Dr. RABI. The object of the mission is to get onto Mars and to get scientific results. That is No. 1. Utilizing this as an example of international cooperation would then be subsidiary. I think it is very difficult in a project as complicated as that to bring in many others because it is difficult and you want success and it is very expensive. You want an organization which is tight, perhaps under a single head. And you would like to have as little as possible of a sort of rivalry which may occur. For that reason I would be afraid of it, particularly if it were international enough to involve the Soviet bloc, simply because of differences in industrial systems, in writing blueprints, everything of that sort.

However, to contradict what I have just told you, at CERN they have built this enormous proton cyclotron, just about the size of our Brookhaven machine, and it cost about the equivalent of $30 million, and parts of it were made by almost every country of the 12 countries which I think were the original members, one chunk or another, and they did it very well, they finished it before we did, and in certain respects it is a better engineered machine than our machine, so it can be done. But I think there you had sort of a romance about it in the sense the industries of different countries decided to do their best, it was all European, which, is another matter, and the principal countries were more or less of a similar size, whereas with the United States cooperating with any other country, except the Soviet Union, it is sort of a horse and chicken hash and it has become very difficult.

Mr. VIVIAN. Dr. Rabi, I would like to point out with regard to my earlier comments on Voyager that the major task of lifting, conveying, and communicating is a task which would certainly have to be done by a single coordinated agency, but the capsule is a device in which there could be many separate experiments. You could get many separate packages put aboard a single entity. I agree with you there are some projects which become difficult without a single point of coordination. However, I disagree with you somewhat on your conclusions with regard to the difficulty of this project.

Let me shift to a different matter. The permeation of science into Europe and into Russia was a relatively straightforward matter in some respects because these nations have been scientifically strong over decades. India and China are two different situations. India has developed a moderately capable scientific community, in fact quite capable. China is developing scientifically as evidenced by their explosion of nuclear weapons. I remember reading Russian scientific material at the end of the war, at the time that the Russians were considered incapable of building anything more than a two by four and they then designed a few items such as ballistic missiles and H-bombs. I have a suspicion that India and China, China particularly, are capable of more scientific effort than we are giving them credit for, having taught many Chinese students in science. Do you have any comments to make on the evolution of science in China and India?

Dr. RABI. It is a miracle to me that the Chinese didn't get to be the greatest scientific nation of the earth. They made so many basic discoveries early in their history. There is no question of their enormous ability. As you may know, in my own department at Columbia we have two Chinese professors; one Madam Wu, who is probably the best experimental physicist—I don't know whether I should add female or not—in the world, a remarkable and charming person, and then, of course, there is Prof. T. D. Lee, who has shared a Nobel Prize. They are simply marvelous people, brilliant, hard working, and charming in every way. I had a fellow graduate student when I was a student at Columbia, his name was Wang, who is now working at the Lincoln Laboratory. He is absolutely brilliant. In fact I have hardly ever come across one that wasn't. There are Chinese all over the United States; in universities occupying very important positions, from Caltech to MIT. So there is no question that this is a remarkably gifted nation, and once they get on the road I think they will be tremendous. There is no question in my mind they will be tremendous because they are industrious and they have the cultural background which is so necessary for both an understanding of science and a contribution to science. If they ever take their rightful place, so to speak, they could be the leading nation in the world unless we really put on our roller skates.

Mr. VIVIAN. It is my impression that they have already taken those steps and they are about to surprise us with their accomplishments. Do you feel that my comments are unwarranted or not?

Dr. RABI. I only regret that we have been unable to go there and see for ourselves.

Mr. VIVIAN. Would you consider it desirable to have a top level scientific team from the United States ask for an opportunity to visit China?

Dr. RABI. More than desirable, I think it is vital, because I think our visits to Russia did an enormous amount to help us understand not only what they were doing but the kind of people they were, something about their connections with the Government and the thrust of that developing culture. Now, we have a new China before us, an entirely new China, but we have no direct experience except fragmentary reports by some English or Frenchman and this is no way for a great country like ours in my opinion to try to understand another great country.

Mr. VIVIAN. Dr. Rabi, I have in the past few weeks suggested to a number of my associates that I feel a top scientific group should visit China at such time as our military relationship is clear enough to be not unpleasant. I even have been interested in taking a trip myself, and I gather you feel that such an effort should be conducted as soon as it is satisfactory between the Governments.

Dr. RABI. If I may digress; I was a member of a committee of five in 1948 of the National Academy chaired by Dr. Bronk who were invited by General MacArthur to visit Japan. We went the length and breadth of Japan, visited different unions and scientists. I think the result of our visit was twofold. We had a much better understanding of the Japanese scientists and their mood and position in the year 1948 at the end of the war, but I think we made an impression and relationships which helped a great deal later on to have these rather satisfactory relationships which we have now.

Mr. VIVIAN. Do you have any comment regarding India in this context?

Dr. RABI. Of course, we have no problem in that respect with India. Our scientists are in and out of India all the time.

Mr. VIVIAN. More specifically, do you feel that we should assist the Indian Government and its private institutions in establishing more active participation in science? I noticed that in a recent film, "Population Control," it was pointed out, I believe by the Indian Ambassador, that the language of science had been one of the very few ways of bringing together the diverse cultures of India itself.

Dr. RABI. Of course, it is very difficult for me to answer anything about India; it is so complicated. There is no question there is a core in India of very high scientific level in science and technology; there is a central core; there are some good leaders; there are very good laboratories, and then there is this great mass of India. I think it would be very good if we could try to help the Indian Government organize itself in such a way that we could help meaningfully rather than have haphazard relationships. That would be a very good thing to accomplish.

Mr. VIVIAN. I would like to switch to a totally different subject, although I have held the floor for quite awhile, Mr. Chairman.

Mr. DADDARIO. You may cover one subject and then we will proceed with the other members.

Mr. VIVIAN. With regard to the diversity of Federal support which is now possible with a large number of agencies supporting frequently parallel activities, do you have any comments or views of the extent to

which this should occur? I realize that most members of the scientific community desire some diversity of scientific support. Do you have any ideas or guidelines as to how much should come from NSF versus some other agency?

Dr. RABI. I was hoping that the NSF role would grow in time to be comparable with the DOD. I think we would have a greater stability. On the other hand, I feel it would be a disaster if the DOD stepped out of the field. There is an obligation on the part of the Defense Department to have its people in close contact, in the close relationships with the scientific community. The only way you can really do that well is to actually support research. The same is true for the Atomic Energy Commission, but somehow we ought, 20 years after the war, to begin to make the civilian side comparable in the support of research and in the support of education.

Mr. VIVIAN. The Director of the Oak Ridge Laboratories was here a few days ago, I am fairly sure you know him.

Dr. RABI. Yes, sir.

Mr. VIVIAN. He indicated that the National Science Foundation support should be well over 50 percent, say, 70 percent. Do you have any comments on these estimates?

Dr. RABI. I am much more empirical. I would like to see us move in that direction and then evaluate the job year by year. I would like to see that become our policy, to let this grow as far as it can without withdrawing too much from the other agencies which need their close contact. Whether it would end up to be 50 or 75 percent or only 40 percent I do not know.

Mr. VIVIAN. Do you see any major new scientific areas in which the National Science Foundation should play an important and increasing role? Are there any areas which you think we are really undernourishing?

Dr. RABI. I like to see the Science Foundation play a role in the high energy field.

Mr. VIVIAN. High energy physics?

Dr. RABI. High energy physics, yes. I feel that we have been backward in exploiting the opportunities in high energy physics. When they start asking the relationship of the support to mission and all that sort of thing, you find it difficult sometimes with respect to other agencies to tie the matter down, whereas since this is pure basic research I would like to see the National Science Foundation get into it. I think they have done an excellent job in the support of radio astronomy and visual astronomy in the form of large national laboratories and so on, and I would like to see them enter the field in a very big way, in two ways in fact.

We need a facility which is so big that it will really represent our best foot forward. I would like to see us proceed as rapidly as possible to making the facility of energy higher than 500 billion volts. My own feeling is that the 200 billion we are talking about is far too small. That can be done by France. I think we should put up something which is really visible and commensurate with the power and qualities which we have. High energy is the growing point of physics, it is expensive, but there are tremendous discoveries being made, and present facilities are fantastically overcrowded.

Mr. VIVIAN. In the 20 to 30 area?

Dr. RABI. Yes. There is just a lot of bad blood being created and competition on that machine. It is expensive but not expensive for us. It would be expensive for a smaller country. But we have to realize how big and wealthy we are and what it is up to us to do, to utilize the circumstances which exist and the tremendous breakthroughs which have occurred in these fields and to exploit them in a significant way. Of course, we would become a magnet for the scientists from all over the world who would come and work.

Mr. VIVIAN. In other words, you would suggest several more Brookhavens at the same energy level and——

Dr. RABI. Yes; and——

Mr. VIVIAN. And the 200——

Dr. RABI. That is too small. It is really not a stopping point. We should go for broke there.

Mr. VIVIAN. How close will be the ones in Europe?

Dr. RABI. They were talking of 300 when they talked of that type. They decided at CERN to make another sort of machine, a storage ring.

Mr. VIVIAN. Does the present American proposal include provision for a storage ring?

Dr. RABI. There is some talk about it. It is not precise. I don't think we have really found a way of talking about these things and planning these things that is good enough.

Mr. VIVIAN. Let me switch you to a different scientific subject. Do you feel that the scientific application of the knowledge of our nervous system and the functions of the brain is receiving adequate attention?

Dr. RABI. It is a field that I deeply respect and admire but I know nothing about. I can't comment. I have heard some marvelous talks, but I would not want to judge the experience in a field which I don't know. If you talk to me about high energy, this I feel in my bones.

Mr. VIVIAN. That is all.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Following this question which Mr. Vivian just proposed with regard to other areas of emphasis by the Foundation, would you care to comment at all with regard to the direction of support for the social sciences as compared with the physical sciences; do you have any views on this?

Mr. RABI. I have heard a great deal of talk about a balanced program, and I don't quite know what it means. I remember when my wife was in college one of the teachers said that she would give this girl an A but to balance the curve she would have to flunk somebody, and she didn't want to flunk anybody, and she did not give her this A. I don't see the support in this way. I think your support comes where things are moving, where progress is being shown. Now, any field in the social sciences that has really shown progress and a breakthrough in understanding I think we should support them for all it is worth, because after all this sort of understanding we need very, very badly, but I would make that as a general principle rather than sort of a balance, that if we give a dollar here we have to give a dollar there.

Mr. Brown. The current level of support for the social sciences by the Foundation is somewhere under 10 percent, and the remainder is going to the physical sciences and the health sciences. I would agree with your philosophy that it is desirable to provide support where it is needed, but I think it is obvious in the past even in the physical sciences we have achieved breakthroughs by giving support even though the need was not as obvious as it might have been.

Dr. Rabi. I don't think the need is so much a measure as the opportunity. Now the social sciences, of course, get a great deal of support from the private foundations which the physical sciences no longer do. I don't know how great the physical science support really is in the sense of where you are supporting people. When we build a big machine, it is the machine, it is industry; the number of people concerned may not be very big although the dollar sign is enormous. I don't know just how to weigh this.

I hope I haven't said anything against the support of the social sciences, it was not my intention, but more or less expressing a philosophy of weighing the kind of support in the sense of opportunity.

Mr. Brown. You made some comments with regard to your own deep feelings about the importance of science as a means of creating the bonds between nations and establishing the conditions under which communications and eventual improvement of relations can take place. This has been true in the physical sciences to a very great extent. I think the physicians have taken the lead in encouraging international cooperation not only among the allies but with the Communist bloc. It seems to me an essential element of the Communist philosophy is that they consider science as the explanation of history and economics and anything else. We do not have a comparable attitude toward the philosophy of science in this country. That is my impression. Would you concur in that? I am not discussing the accuracy of their own self-image with regard to their role but merely posing a general question.

Dr. Rabi. Well, there were various reasons why people did science. If you go back in history, one made these discoveries for the greater glory of God. Another way of looking at it is an example of the spirit of man. Still another way of looking at it is that here we are in this universe, this is our home: we have to find out as much as possible in order to live, to understand how to live right and to protect ourselves against the elements, against nature. Furthermore, it is a very high intellectual expression. And looking further into the future, perhaps not so far, when our technology has advanced so that the working day is shorter and shorter, and you want to hold up something for the youth of this country which will be a real challenge for them, not just to run faster or have a lower golf score, a faster car or whatever, eat seven meals a day, there is only one field, there is only one field which has an endless frontier, an inexhaustible challenge, and that is science, nature in its profundity, in its infinity, in its tremendous variety: that is the challenge. That is the ultimate challenge for a civilized country. I hope we will get to the point where we solve many of our housing problems, clothing, food, whatnot, and have a population that is excellent in physical well-being, but unless they are given some challenge of this sort, they will revolt out of boredom. I

regard science as the thing for us to do and to press on, and at some time or other I expect that we will be expending a very considerable portion of our product, our total effort in the scientific field. It may sound far out.

Mr. BROWN. I am not sure that answers the question that I asked, but I will raise another question. I feel a great deal of sympathy with what you have just said, but you are touching on a matter of the relative importance which a society gives to various elements in that society. This becomes then a matter of culture. What in that culture is valuable? We give value to science over here not for the cultural reasons that you have expressed, but because it enables us to produce more Cadillacs and more air-conditioning units and various things of that sort. I am not sure that emphasis upon the physical science is going to change that aspect of our culture.

Dr. RABI. That aspect of our culture goes way back to the origins of the country. Benjamin Franklin, who I still think was the greatest scientist ever produced in America, spoke that way. He made tremendous advances in theoretical science in the understanding of electricity. However, we are changing and developing. In a country which had to conquer a continent we, of course, had to have that. We are changing very rapidly. The American mathematicians are among the most abstract mathematicians. I can tell you, sir, that within my own period, in my own lifetime, the country is almost unrecognizable when you come to the field of science and education. So I think we are bound to go that way. But fortunately also we are not alone in this world, and the competition with Russia and the Communist countries is going to be very good for us and has been. Look what sputnik did for us. The greatest thing that happened to the United States in recent years was sputnik in the sense of spurring us to a better effort, to a greater effort, reforming our education, making us more aware of these very questions, I don't think that the other countries will let us rest on our laurels, and I am quite sure that given enough time for reflection we are going to support science even more fully in the future than we did in the past, both for our own interest and because of the competition of other countries.

Mr. BROWN. The point you raise is exactly what I am afraid of. I think you describe science as the physical science in the area of competition in the spectacular between ourselves and Russia; the sputniks, high-energy physics, and that sort of thing, when the basic problem that confronts the world today, and I am talking about the Communist and the free world, is the problem in competition involving the underdeveloped world. The underdeveloped nations are not interested in how many sputniks or how many high-energy accelerators we can produce. They are interested in some very fundamental problems such as how you organize elementary education, better agriculture, a more effective or efficient governmental bureaus, and a whole gamut of very unspectacular things. I am afraid that the emphasis we place on the spectaculars in the physical sciences in response to the competitive effect from Russia may be detracting from our ability to compete for the two-thirds of the world that don't care about these things. I am interested in determining if there might be some reason for changing this.

Dr. RABI. I just can't agree with you because as a result of those advances we are just beginning to have the tools to understand our economy, with these computers and these devices, which will enable us to understand the workings of social systems with a large number of ingredients, and the Russians are just beginning to copy us in this respect. I think some of the developments of economic theory in this country and its application and use with modern machines is going to have a tremendous effect on the Russians in this way, not only in economics but in the general theory of the operation of social systems. I think it will also enable us to understand better how we could help the underdeveloped areas. These are just tremendously difficult problems because the whole cultural side has to be involved and the resources and a vast number of factors have to be understood and weighed. I do not believe that social theory, as such, abstract theory, will develop very rapidly. It hasn't. But on the other hand, by studies of the sort, particularly through the use of computers, where you can handle a vast amount of data and try out various ideas, we may have a much more profound understanding of these very questions. We may even be able to understand how our own systems work, which is a miracle and has always been a miracle to us. To me one of the great spectaculars, and will continue to be in the future, is the development of these devices which will enable us to understand what is going on.

Mr. BROWN. Your point is that if we put more money into research in accelerators, computers, sputniks, and Martian probes, there will be a trickle down into the social sciences.

Dr. RABI. You may have to make these devices accessible. That is the important thing. There has to be enough of them, to have enough money in it, enough schools to give instructions on how to use them. You can see how these computers have been lapped up by business. This is how they find out what to do, how to make their policies which they never did before. It is not just a trickle down. So, very often you have devices which have been invented for scientific purposes, very often the physical sciences, which then find this tremendous application in other fields. That has been true all along, and I think it will be true in the future.

Mr. BROWN. Mr. Chairman, I won't pursue this further, but in connection with another point, may I ask if the committee would be able to get information from the DOD with regard to the DOD funding of foreign science education and research?

Mr. DADDARIO. We can get that information.

Mr. BROWN. I want to know, in line with the comments that were made here, the amount of funding for foreign science, basic research, and education, and correspondingly the figures for the military funding of their own military education and management practices with foreign nationals. In other words, how much money is being spent to train foreign nationals in military science and related problems.

Mr. DADDARIO. We can get those questions answered for you, Mr. Brown.

Mr. BROWN. I want to compare the relative impact of DOD in the fields of basic science, research, and military activities.

Mr. VIVIAN. Mr. Chairman, we have a witness coming before us next Tuesday, a Mr. Pollack, Acting Director of International Scien-

tific Affairs for the State Department, and I would be interested in these comments by the time he arrives. I think it is along the same lines.

Mr. DADDARIO. We will see if we can get them. I should think they would be readily available. Some years back we made a study in this field. I am sure we can build upon those.

(The following information has been submitted by the Department of Defense:)

DOD does not sponsor any foreign science educational programs with research, development, test, and evaluation funds. In 1964 we did obligate some $401 million with U.S. academic institutions from R.D.T. & E. appropriations. Since foreign graduate students are being educated at many of these institutions, some fraction of them undoubtedly participated in the university research and development programs supported by these defense appropriations. However, we do not maintain records within the Department of Defense from which the fraction of DOD support pertaining to foreign graduates could be obtained.

In fiscal year 1964 our total obligations for foreign research and development amounted to $29,275,000. Of this amount, only $9,441,000 was obligated for research in foreign academic and nonprofit institutions. Two-thirds of this amount ($6,225,000) was obligated for basic research. Certainly some fraction of this amount supported research activities of foreign graduate students; yet, as in the United States, we are buying research results and graduate education is not an objective in our programs. Thus, we have no records indicating either the number of foreign graduate students involved or the fraction of funds utilized for graduate student support. Generally, even the original research proposals do not yield any clear identification of these research assistants who are also graduate students.

Regarding the allocation of funds to the training of foreign military personnel, figures extracted from the military assistance training program for the past 3 fiscal years are as follows:

[In millions of dollars]

Funding categories	Funds programed by fiscal year		
	1964	1965	1966
Student training[1]	46.6	41.0	35.1
Mobile training teams[2]	4.8	4.6	2.6
Contract technical services personnel[3]	7.1	4.9	2.9
MAAG and Command training support[4]	25.3	23.5	22.2
Other training support[5]	8.5	8.1	9.7
Total	92.3	82.1	72.5

[1] Student training encompasses all instruction given in formal training courses and in orientation training, both in Conus and overseas.

[2] Mobile training teams are small groups of U.S. military specialists sent to foreign countries for periods of not to exceed 6 months for the purpose of conducting training with the indigenous forces.

[3] Contract technical services personnel are civilian technicians, under contract to the U.S. Government, who are sent to foreign countries to conduct training in highly specialized skills (such as maintenance of aircraft and electronic equipment) not available from U.S. military resources.

[4] This includes the operating expenses of the military assistance advisory groups which are attributable to the overall training effort.

[5] Includes expenses related to training of military personnel for their MAAG assignments and reimbursement to Department of State for activities associated with the training effort overseas.

From the above it can be seen that costs most directly attributable to the training of foreign nationals are those listed in the first three categories; i.e., student training, mobile training teams, and contract technical services personnel. The funds programed for this purpose in fiscal years 1964, 1965, and 1966 amount to $58.5, $50.5, and $40.6 million, respectively.

Mr. DADDARIO. You have envisioned a greater role for the National Science Foundation. I imagine when you speak of the flywheel maintaining an even level, you are referring to the National Foundation

as playing that part. You suggest that the National Science Foundation become more involved in high-energy physics. How would this work in relation to the present atomic energy program?

Dr. RABI. It is difficult to be entirely responsive to your question. I certainly would not suggest anything drastic to be done immediately because an organization has to be built up so it can handle these matters, and what I am talking about involves a large amount of money. I should hope that by starting in some subject in a cooperative way; let us say, with the Atomic Energy Commission, then there could gradually be the shift over of some projects into the National Science Foundation. For example, we have a cyclotron at Columbia which was built with the cooperation of the—well, I won't go back to the cyclotron. We have a laboratory called the Columbia Radiation Laboratory, which was started with the Office of Naval Research and gradually became a three-service organization. There have been large cyclotrons which were started at one agency and then became a cooperative project and then went on over to another agency in the end. It was a question of funding and which agency would have the most appropriate interest. This I would suggest would be the direction in which the National Science Foundation should get into things to get its feet wet. First, it has to have some money so as to contribute. In this way they will acquire the management skills necessary for that project, the staff, and ultimately they might take over some of them. I wouldn't suggest it is something which should happen overnight or in 1 year.

Mr. DADDARIO. Your suggestion is that the National Science Foundation analyze areas of opportunity and become a greater participant in these. Even though you don't contemplate that the Department of Defense will step out of any of these fields, you indicate that because there are fluctuating budget problems over the course of time, this might find the National Science Foundation in a necessary role of filling in these gaps?

Dr. RABI. Exactly.

Mr. DADDARIO. Dr. Rabi, we have had some correspondence from the American Institute of Physics, in regard to foreign participation. There is one paragraph in a letter we have had from Van Zandt Williams, the director, and I would like to quote it to you and ask for your comment:

> Our correspondence with U.S. physicists on long-term appointments in developing countries shows that they may have seriously endangered their position in the academic ladder at home. We believe both United States and world science would benefit from measures that encourage qualified students to enter foreign service and that help them to retain their professional standing. We endorse programs that link research programs of foreign universities to those in the United States.

Would you comment upon the fact that our physicists are endangered by such participation and what might be done about it. I imagine you agree with the other comments in that paragraph.

Dr. RABI. It is natural, isn't it, that when a man is absent for a period of time life must go on and he is replaced in one way or another, and if he is given leave of absence and he comes back, he must again construct a niche for himself in the operation of any university department or any organization. They have moved on, the things which interested him are no longer the same, and he must find another place.

This has been very difficult, and is one of the great difficulties in having, let us say, a scientist come to work for the Government, this Government or any other government. After a few years he comes back, and as the Bible says, "There arose a generation which knew not Moses." He had to find his place again. He has to get students to do research; graduate students. His courses has been taken up by somebody else. He may have to displace them or make up a new course, and all that sort of thing, so there is an inherent difficulty. I see no way of solving it except to suggest that if the gentleman played a wider role within his institution, then he could take up a new job using his new experience.

Mr. DADDARIO. Could there be a possibility of retraining?

Dr. RABI. I didn't mean so much that he has fallen behind, although that is true, too, only that his work has been taken over by somebody else. If a man is going to be gone for 3 or 4 years, there are certain courses that will be taken over, a whole generation of graduate students will come along that have never heard of him. He returns with a different experience which should be utilized somehow. It is very hard and I have no very good suggestion. I can just give you an example of what happened during the war. We had a laboratory, the radiation laboratory in Cambridge, Mass., where I was associate director of the laboratory. We had a branch in England. We would send a man over there, a group of men, one man to direct it; let us say, he would come from a very high level within the laboratory itself. He would be gone for a year or so and then it was very hard to fit him in again. He may have been the head of a very important division but somebody else was running it. We had to find a new job for him. It became very, very difficult unless you have an expanding organization. In an expanding organization, of course, he can come right in where there is more to do. I believe on the whole it is going to be a very serious organizational administrative problem of how to handle this. I think is is not only true of the scientific field, but I think it will be true in other fields, too.

Mr. DADDARIO. You encourage that activity and yet you recognize that these men might possibly make a greater sacrifice than perhaps they might have intended in the first case?

Dr. RABI. Oh, yes. I knew it happened to me in my own case, when I began to come to Washington a great deal for the Atomic Energy Commission, and I was not seen so much around the halls of Columbia, so students didn't come to me to get their doctor's degrees and pretty soon I was in trouble, although I did a good job for the United States—I hope I did—I wasn't doing a good job for those students at that particular time. It is a very, very serious matter.

Mr. DADDARIO. Professors have fence-mending problems, too, Doctor?

Dr. RABI. Yes, sir.

Mr. DADDARIO. We have many more questions we would like to ask you, but we are summoned by a quorum call.[1]

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

I hope we will be able to send some additional questions to you. We will try to make them reasonably short. I want to thank you for having come. It has been a very helpful contribution you have made, Dr. Rabi.

Dr. RABI. Thank you very much.

I have enjoyed being here.

Mr. DADDARIO. This committee will adjourn until 10 tomorrow morning at the same place.

(Whereupon, at 12:50 p.m., the committee was adjourned to reconvene at 10 a.m., Wednesday, July 14, 1965.)

NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JULY 14, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order.

Our first witness this morning is Dr. Harvey Brooks, who is the dean of the Division of Engineering and Applied Physics at Harvard University. Dr. Brooks has been extremely helpful to this committee in the past. We are very happy to welcome you here, Dr. Brooks, and anxious to hear your testimony.

STATEMENT OF DR. HARVEY BROOKS, DEAN, DIVISION OF ENGINEERING AND APPLIED PHYSICS, HARVARD UNIVERSITY

Dr. Brooks. Thank you, Mr. Chairman.

I will try to go through my written testimony, perhaps omitting some things in the interest of time. As far as procedure is concerned, I would be perfectly happy to be interrupted by your committee as I go through, or to go right through, whichever you prefer.

First of all, Mr. Chairman, I should like to express my appreciation for the invitation to appear before your committee and also my admiration for the thoughtful and responsible way in which your subcommittee has succeeded within a short time in penetrating the complex and difficult issues surrounding the involvement of our Government with science.

With your permission, I should like to make it clear that I am appearing before you in my capacity as a private scientist, and not as a member of the National Science Board, a consultant to the Office of Science and Technology, an officer of the National Academy of Sciences, or even as a Harvard dean. These various hats are not without their influence on my views and help to provide a certain amount of perspective, but I want to make it quite clear that my views do not necessarily coincide with those of the officials of any of the institutions, governmental or private, with which I have some connection.

On the other hand, I would not wish this disclaimer to lead you to expect a sweeping attack on the system of science policy in the United States, or a proposal for radical reforms, for in point of fact I find myself very close to Dean Price, who has testified earlier in these

hearings, in my belief that the system is in very good shape indeed and that, in particular, the National Science Foundation has been a far more constructive and creative force in American science than anybody could have anticipated in the light of the bitter debates and questions that preceded its creation.

You have asked me to address myself to three questions, Mr. Chairman, and I should like to begin by taking these up in the order in which you suggested them. The first refers to criteria of support for basic research. Here I would remind you that I have already set down my views at some length in the paper I prepared for the report, "Basic Science and National Goals," which was prepared for your committee, under the auspices of the National Academy. Today I would like only to underline a few salient points.

In talking about criteria, I think we have to distinguish between three rather different types of basic research in accordance with the type of institution in which it is performed. The three classifications I have in mind are establishment basic research, programmatic basic research, and academic basic research.

First, establishment basic research: There are many Government laboratories or Federal contract research centers with applied mission objectives which nevertheless devote a significant proportion of their total budgets to basic research activities, much as is done in some of the larger industries. This type of work probably constitutes more than 30 percent of all the basic research funded by the Federal Government. Examples are laboratories like Los Alamos or Lincoln Laboratory or Federal laboratories like the Naval Research Laboratory or the National Bureau of Standards.

Second, programmatic basic research: This is the kind of basic research which is sometimes referred to as "big science." It may be defined as organized basic research carried out in an institute established for a programmatic purpose which is related primarily to a specific area of science, rather than to an applied or technological objective. Often such institutes, like the Brookhaven National Laboratory or the National Radio Astronomy Observatory, are established to supplement the work of universities and to provide facilities for university scientists.

One may distinguish two types of programmatic research institutions:

(*a*) Those organized around complex and expensive equipment or instrumentation requiring extensive "care and feeding" by a skilled permanent professional staff. Examples are accelerator laboratories, optical or radio astronomy observatories, laboratories of oceanogaphy, etc.

(*b*) Institutions organized primarily to bring together a "critical mass" of scientists usually from different disciplines to carry out a cooperative attack in a defined area of basic science. It is characteristic of such an institution that in some sense it can be said that the whole is greater than the sum of its parts. The National Center for Atmospheric Research is an example of a laboratory primarily of this character.

The line sometimes between what I have termed "establishment research" and "programmatic basic research" is often hard to draw.

For example, several of the AEC national laboratories, such as the Argonne and the Los Alamos Laboratories, have activities which are clearly establishment research, but they also have separate activities in high energy physics, for example, which are sufficiently separate so that one might properly identify them separately as a programmatic basic research activity.

Thirdly, the category of academic research. This category actually comprises both basic and applied research conducted primarily in connection with the training of graduate students or other research personnel, usually within a university science department or professional school. It would include departmental research in engineering, medicine, and agriculture. It is characterized by being primarily individualistic in approach generally related to the research idea of a single individual, working with a small number of students or associated. I might add parenthetically I think one could also distinguish two categories of academic research which might be classified as mission-oriented academic research and discipline-oriented academic research. By mission-oriented academic research I mean academic research supported by agencies with applied missions for the primary purpose of keeping, as it were, a window on the world of science in order to take advantage of it in their technological activities. Discipline-oriented basic research is basic research supported primarily from the standpoint of developing certain scientific disciplines. Of course, the research of the National Science Foundation is the best example of research which is supported from a disciplinary point of view in that sense.

Unfortunately, these three classifications are only approximate, and there actually exist many intermediate cases. For example, an experiment in high energy physics usually begins as an idea in a university, and the initial instrumentation is designed and built by a professor with a few graduate students, and then, after exposure at a big machine, later interpreted and reported in the home laboratory. Similarly many of the most important experiments in space science have been conceived and designed in relatively modest university facilities before being put aboard a satellite. In each of these examples, however, there is an essential interface between the "little science" and "big science" aspect of the experiment. Before the experiment can actually get time at an accelerator or find a place in a satellite, it has to be approved by a committee and then programed, so that it ultimately requires substantial leadtime and cooperative effort as well as large supporting facilities and staff. The preparatory stages might well be classified as academic research in each example, whereas the actual programing of the experiment must be classified as programmatic research. These two aspects can often be kept separate in financing.

Programmatic basic research, whether or not it requires large and complex installations, is usually characterized by a high ratio of supporting semiprofessional staff to independent researchers, typically as high as 5 to 1 or even more, whereas academic research is usually characterized by more like a 1-to-1 ratio of supporting to scientific staff.

All the three types of basic research mentioned above are essential to the health of our national science and technology. Furthermore, they are closely interrelated, and depend upon rather free circulation of people between the various categories, as well as between basic research and technology. On the other hand, I feel their total funding should be determined by somewhat different criteria and by somewhat different mechanisms.

To add programmatic research and academic research and call this total research is in some sense somewhat meaningless. The choices involved in the funding of both establishment research and programmatic basic research should be much more explicitly political than the choices in the funding of academic research, although obviously the total funding of academic research has to be a political choice as well.

With respect to academic research as a whole the National Science Foundation currently funds only about 13 percent of the total of slightly over $1 billion—this is the category that is usually classified in the statistics as research in the universities proper—although in the future I would like to see this grow to something of the order of 25 percent. I believe it would be undersirable for this to grow to much more than 30 percent for academic science as a whole, and not more than 80 percent for any one field of science, for much of the strength of our system of support for academic research depends on its diversity, on the competition among agencies to seek out and support the best science and the best people, and to provide the most favorable conditions for creative work. When it comes to the support of basic science I am very much an antimonopolist. Assigning exclusive responsibility for a given area of science to a single agency may look good for administrative neatness, but it is the surest guarantee I know of for intellectual, and usually consequently also financial stagnation.

Mr. VIVIAN. Mr. Chairman, I would like to ask Dr. Brooks if he could explain the relationship between the 25 to 30 percent on the previous page and the 80-percent figure which is given for the total support in the field of science.

Dr. BROOKS. The 30- to 35-percent figure really referred to the totality of academic research. I believe it would be unwise for the Science Foundation to be responsible for more than 30 to 35 percent of all of academic research.

Mr. VIVIAN. Can you tell me why you picked that particular number?

Dr. BROOKS. It is somewhat of a number pulled out of a hat.

Mr. VIVIAN. Dr. Weinberg, for example, came up with a figure of 70 percent. I thought that was a bit high, but I think 35 percent is a bit low. I am not objecting, but I am curious to know how you established the number.

Dr. BROOKS. I really established it from a number of qualitative considerations. On the one hand, both from the standpoint of the health of science and also from the standpoint of the health of the scientific programs in the mission-oriented agencies, such as Defense, Space, and so on, I think it is important that they support enough of academic research to maintain a close connection with the academic institutions and with the academic scientists. That I think is one consideration. The other is that I think as much as 70 percent of

academic research being dependent on a single agency runs much greater risk of that bugaboo—Federal control of academic institutions. The plain fact of it is competition among agencies does induce greater freedom of action, greater autonomy in the institutions which are being supported. It is very hard for me to justify quantitatively the number of 35 percent or 30 percent. This is just a visceral feeling. It is three times as much as the present 13 percent, and it is still under 50 percent, and I think this is the best answer.

Mr. DADDARIO. Mr. Vivian, it is my recollection that Dr. Weinberg was referring to the support of basic research in toto and not just academic.

Mr. VIVIAN. Yes; that is correct.

Mr. DADDARIO. So there may not be a proper relationship between the figures.

Mr. CONABLE. I think he also started out with the statement that he would like to see it more than 50 percent, but he did not say 70 percent exactly.

Mr. DADDARIO. After Mr. Vivian had talked with him he said the figures were sliding, but anything over 50 percent would be all right. When we compare Dr. Brooks' figures with Dr. Weinberg's, we ought to be certain we are talking about the same thing.

Mr. VIVIAN. I had the impression that Dr. Weinberg meant roughly the same category, but I don't think anyone has an exact percentage. I am really trying to find out the thought process that went behind these percentages.

Let me take solid state physics, which you are familiar with and which we all agree is an essential field of science for many, many years to come. What percentage of that, for example, would you like to see supported by NASA, AEC, DOD, NSF, and so on?

Dr. BROOKS. I think in that particular field I would argue for something like 60 or 70 percent supported by mission-oriented agencies primarily because these agencies are each so dependent on solid state physics and materials. In other words, it is partly the degree of dependence of the missions of these other agencies on a particular field which I would use as a basis for argument for the total percentage of support that should come from the mission-oriented agencies. On the other hand, astronomy, for example, might well be largely shared in support between NASA and the Science Foundation, and in that field I wouldn't be unhappy to see the Science Foundation have as large a share as, say, 70 percent. In other words, it depends on the relationship of the particular field of science to the mission.

Mr. VIVIAN. In addition to the difficulties with percentages, there is a difficulty in labeling. For example, I concur that a great deal of the applied research or advanced research could be done in these mission-orientated agencies and the rest could be done in NSF. I realize distinguishing labels is a difficult task. Do you have any comments on these intermediary levels?

Dr. BROOKS. Certainly the things that are close to the applied should be done in the mission-oriented agencies but the difficulty particularly in a field like solid state physics is that the line between basic and applied is extremely dynamic and changing very fast, and, therefore, unless the mission-oriented agencies are reaching very far into

the basic end, they are extremely likely to miss the boat. So I think I would still stick to my general rule of thumb that I think in that particular field something of the order of 60 percent of the field would not be at all unreasonable to be supported by the mission-oriented agencies.

Mr. VIVIAN. Thank you.

Mr. DADDARIO. Would you continue, please, Doctor?

Dr. BROOKS. I know one of the questions your committee is interested in is whether the National Science Foundation ought to be less passive in its approach to the scientific community and exercise more leadership in developing new fields or in transferring funds from one area of science to another on the basis of some preconceived set of national priorities. It may be that the National Science Foundation has been too conservative about exercising initiative in the past, but I would hate to see it err in the other direction. The use of "proposal pressure" as a measure of the needs of a given field of science has, in my opinion, been somewhat maligned, and I should like to say a word in its defense. I admit that it is open to abuse. An unscrupulous program officer could in principle manipulate "proposal pressure" from his scientific constituency in such a way as to build up his field at the expense of others, but I seriously doubt whether this kind of gamemanship could go undetected for very long, if only because of the reaction from other fields. I actually know of no instance in which it has ever been really effective. A capable and sophisticated program officer knows how to temper the index of proposal pressure with his own judgment and knowledge of the field. Supplemented by such considerations as the reports of National Academy committees and other panels, I believe proposal pressure is still the best measure we have of the relative needs—and I emphasize the word "relative"—of different fields of science, and I would hope that it would continue to be the primary though not the sole basis of judgment, in the National Science Foundation at least, in the allocation of funds within the category of basic research support grants. Basically it is the system of allocation most likely to lead to the most rapid scientific progress because it is the measure which comes closest to utilizing the day-to-day judgments of the individual working scientist.

On the other hand, I think there are real needs for other mechanisms of support in addition to the project grant system. I believe the science development grant is a step in the right direction. On the other hand, I feel this whole program will lose its point and purpose if the basic research support grants both of the National Science Foundation and of other agencies are not increased to take care of the new capabilities which will hopefully be created by the science development program. Although the institutions which benefit from this program expect to take over support for the new faculty and facilities created, not one of them expects also to take over the financing of the new research capability which is being created. These institutions expect to compete on an equal basis for basic project grants, but it will not serve the purpose of the program if more and more institutions simply compete for a share of a fixed budget. The total financing of all higher education from all sources and at all levels increased at a rate of over 12 percent a year from 1960 to 1963—and I suspect has been increasing even faster since 1963—and only slightly less than 12 per-

cent during the preceding 6 years. With the rapid growth of student population, this growth is likely to accelerate. As a proportion of this total, academic research has increased from about 9 or 10 percent to about 13 percent over a 10-year period. This is a fairly modest increase when one considers the growing importance of graduate work. Actually much of this proportionate increase has been due to the rapid growth of the biomedical sciences, and in terms of the other sciences the proportion of research to total expenditures for higher education has remained probably nearly constant.

Furthermore, contrary to some statements which have been made, non-Federal sources of support have largely kept pace with Federal funding if one confines one's attention to basic research and to "little science." Thus while I look forward to a somewhat more rapid growth of institutional-type grants, the basic research project grant must also grow and grow substantially in the next 10 years if our total system of higher education is to remain healthy and viable.

Mr. VIVIAN. With reference to your statement that non-Federal sources of support have largely kept pace with Federal funding, do you mean non-Federal sources of university research or non-Federal sources of industrial research?

Dr. BROOKS. I am talking about university research. I mean non-Federal sources of university basic research, and I stress the word "basic" because if you look at the total funding of university research, the proportion of Federal funding has increased, but this has been largely due to increases in the applied research area. Apparently the proportion of Federal funding of university basic research has remained about constant during the last 10 years as near at least as I can interpret the statistics.

Mr. VIVIAN. Do you have any information on the Federal support of industrial and allied research outside the universities?

Dr. BROOKS. Yes; I have impressions. I would have to look up the figures. The proportion of Federal funding has certainly increased for industrial research, and just as a very rough recollection in 10 years I think it has increased from about 40 percent of all industrial research to about 60 percent, something of this order of magnitude. I think it has been a switch of 60–40 over a 10-year period of industrial research.

Mr. MOSHER. Do State funds play any important role at all in those non-Federal sources? Is there any tendency among some of the States to increase their direct appropriations for academic research?

Dr. BROOKS. Yes; this is something that I don't have any very clear information on and one of the things I hope to find out more about this summer. It certainly is true that State appropriations for higher education and for research in the universities have been a major factor in the non-Federal sources of support, but just how major a factor is not too clear to me.

Mr. MOSHER. I am sure they are increasing for higher education purposes in general, but I wonder whether States actually earmark funds for research.

Dr. BROOKS. One thing that somewhat confuses the issue in this particular statistic which comes from the NSF so-called intersectorial transfer statistics is that the total includes agricultural research funds, and since these are on a 4-to-1 matching basis for the Federal grants,

this tends to swell the percentage of non-Federal support in the total research picture. One piece of information which we certainly don't have is, for example, how non-Federal sources break down as between private universities and public universities and to what extent non-Federal sources is accounted for by the agricultural matching program and so on. We don't have any real, at least I don't have any real understanding of these relationships as yet.

Mr. DADDARIO. Will you continue, please?

Dr. BROOKS. Coming back, then, to the question of criteria for basic research support let me suggest a list of criteria for each of the three classifications of basic research I have sketched.

(1) ESTABLISHMENT RESEARCH

How much basic research is needed and what basic research is relevant for the achievement of the long range—and I stress the words "long range"—applied mission of the establishment should be primarily a decision of the local management. The departmental administration which supervises the establishment and defends its budget should anticipate that some proportion of the total funding would be spent on free basic research which the establishment director thinks is appropriate. The proportion so spent should be influenced by the following considerations in approximate order of importance:

(*a*) The degree to which the technology used by the establishment in its applied work is dependent on recent advances in basic science.

(*b*) The apparent relevance, as judged after the fact, of the basic research project actually undertaken to the long-range goals of the establishment.

(*c*) The degree to which the basic research program is integrated with and actually stimulates and vitalizes the applied effort. In particular the basic scientists should not be insulated entirely from the applied work and should be available for consultation and should understand and be interested in the applied goals of the establishment.

(*d*) The past performance and achievements of the establishment as related to its applied mission.

(*e*) The competence of the personnel for basic research. However, individual performance in basic research alone should not be as important a factor in the judgment as for programmatic or academic research. Some basic research may be necessary to the total success of the institution, even though it may not be of the very highest quality as judged by usual scientific standards of originality and generality.

(2) PROGRAMMATIC RESEARCH

Here the most important choice is the initial commitment for the creation of a new research institution. Some of the criteria that should be applied to this initial—what I call "strategic"— decision are the following:

(*a*) The availability of able scientists who believe deeply in the program and are willing to stake their personal scientific reputations on its success through actual participation.

(*b*) A convincing argument that the programmatic objectives cannot be achieved as well through existing research institutions or facili-

ties, and that the proposed institution will create a capability which is essentially or nearly unique.

(*c*) The availability of sufficient finance, including a reasonable anticipated rate of growth, and of sufficient competent people, to assure continuing significant contributions to science as judged by a worldwide standard of excellence. Such a project should not be started if its continuing adequate financing implies cutting of support or stagnation of support for other scientific fields or for academic research generally.

(*d*) The novelty and intrinsic intellectual significance of the scientific results it is hoped to achieve.

(*e*) The contribution to and relevance to other important areas of basic science, either current or anticipated.

(*f*) Potential contributions to future technology either directly or indirectly through the qualitative nature of the demands placed on technological capabilities.

(*g*) Contributions to the education and training of future scientists and technologists.

(3) ACADEMIC RESEARCH

The total financing for academic research should be geared to a national policy for the growth of higher education. The research program should be such as to provide significant research experience for all students who are qualified, and in numbers consistent with the national policy. It seems reasonable to expect that Federal expenditures on academic research should expand somewhat faster than total national expenditures on higher education as a whole simply in view of the growing relative importance of advanced research training in higher education and the increasing sophistication of research. In general the fields in which support in provided should be responsive to the interest of scientists rather than explicitly to politically determined national needs, in contrast with establishment of programmatic research where applied needs should be a relevant consideration. Academic research should be biased toward national needs only indirectly through publicizing and explaining such needs and the consequent career opportunities and depending on this information to influence the desires and interests of academic scientists, and hence the demand for research support. The special virtue of academic research from the standpoint of society lies in its individualistic character. Not all academic research need necessarily be of this individualistic character, but it should be predominantly so, and the preponderance of individualistic type research should be carried on in academic institutions. Whether the individual research projects are selected by committees of peers or by the institution itself, the criteria for support should be the same.

Mr. DADDARIO. How do you translate that into action? You establish the criteria. You stress the importance of selection of the individual research project by a committee of peers or by the institutions. Where do you translate this to the point of taking political action? Even though the decision should be within the scientific community, how do you get the funds to do the project, and how do you stir up interest in the program assuming that the scientific community can come to a judgment as to priorities?

Dr. BROOKS. What I am trying to say I think is that within academic research the priorities should be determined primarily in terms of what one might call the market demand modulated, of course, by publicity through such things as national academy reports and so on. I think what I am trying to say is that the virtue of academic research lies really in the fact that the initiative and the ideas and so on come from the individual working scientist, that it is his ideas and his sense of priorities which should primarily govern the allocation of funds within this particular area.

Mr. DADDARIO. How do you reconcile this with the proposal that there should be some basic research which might not necessarily be of the very highest quality in academic research?

Dr. BROOKS. That was referred to under establishment basic research. The criteria that I am talking about here refer to academic research. Perhaps you were asking me about my earlier set of criteria. I was suggesting that somewhat different sets of criteria, particular priorities among criteria, should apply to the three different classifications of basic research. They require somewhat different defenses in relation to the total budget. In other words, with respect to establishment research I made the point that individual excellence of performance might not have as high a priority in connection with establishment basic research as it should have in connection with academic research. It may be necessary to have a certain amount of basic research going on in a mission-oriented establishment even though the quality of that research might not compete effectively, let's say, in the academic marketplace. In other words, different criteria should be applied to establishment basic research than to academic and programmatic research, but the judgment on this of what should be done here I think should be primarily in the hands of the management of the establishment within his total allocation.

Mr. BROWN. We are still talking about Federal support for individual research. I have a feeling that the health of basic research is going to depend upon having a certain number of scientists who are willing to devote themselves to research with no Federal or private funding, but merely research stemming from their connection with the university and its opportunity and their feeling of what is important whether or not they can get funding for it. Am I completely off base as to the desirability of this kind of individual basic research?

Dr. BROOKS. No. Let me—if I could digress on that a moment—I think there is very little basic research today that can be done without some source of funding, whether it be private or institutional or Federal. Perhaps there is some work in pure mathematics which can still be done sitting with a pencil and paper in a dark room provided there is somebody to pay the mathematician's salary, which is presumably the local university, but there are relatively few areas of basic research that don't require some extra source of funding, whether it be institutional or from sources outside the institution. I think the kind of independence that you have in your mind can be achieved to some extent if some of the total funds available for basic research are at the disposal of the institutions or the department, so that an individual, especially the more maverick type of individuals, is not completely dependent on going to some Federal agency in order to get support for a particular project, particularly a project that may not in fact be very well thought out in advance.

Mr. BROWN. What is the role of the basic research which is carried on by members of a university faculty as part of their ongoing professional responsibilities of both teaching and research which is supported because they are on the university faculty. In other words, the researchers don't receive special money from the Federal Government or any other source, they use the time and the resources of the university which are available to them, and they investigate projects or problems which they think are important. Isn't this going on any longer?

Dr. BROOKS. There is a great deal of this going on, much of it with Federal financing.

Mr. BROWN. What do you mean "with Federal financing"?

Dr. BROOKS. Very little of the research that is going on in the university department, even that which is federally financed, is done other than at the instigation and the initiative of the individual faculty member in the university. Usually he gets started on it with university funds and then it grows to a point where university funds are inadequate to carry on the work, and then he seeks other sources of support, depending on what is available. I think the sharp line that you draw between the individualistic research supported entirely within the university and research which is supported by the Federal Government is really not a very realistic line, it isn't that different. One merges over into the other. Even in the federally financed research the salaries of the faculty members and so on are usually financed by the university and the Government contributes technical help, machine shop time, computer time, all the other kinds of things which are now even in the social sciences needed to support a viable research activity. So there is a merging together of these two sources of support, and I don't think you can really draw a sharp line.

Mr. BROWN. What I am looking for is the gate mentioned in your comments that all research has to pass through. This gate seemed to imply that there is no place for research which isn't selected either by a committee of peers or by some other criteria.

Dr. BROOKS. I think in all honesty one has to say that all research that is done in a university is selected in some fashion. Even that which is selected by the individual is selected in a sense. Whether or not the individual received promotion or received an appointment on the faculty in the first place depended on a selection process. So selection is going on at all stages in the system of higher education, whether it is selection of individuals for fellowships or for staff appointments at a university or whether it is selection by a university administrator as to what work or what requests for equipment and so on of a departmental member will be supported and what requests will not be supported. The demands for support, the needs are always much greater than the funds available, whether they be institutional funds or Government funds, or whatever the source of funds, and some selection process has to go on at all levels, whether it be within the university or within Federal agencies. I mean the idea that the university faculty member is completely free to do anything that he wants is inversely proportional to the cheapness of what he wants to do. If it costs money, somebody has to select who gets the money and who doesn't, and it may be within the institution or it may be outside the institution, but there is a selection process going on throughout the system.

Mr. BROWN. I guess I am just old fashioned.

Mr. CONABLE. Wouldn't it be fair to say that a lot of the basic research that he is talking about is involved in simply the preparation of proposals for securing funding of one sort or another?

Dr. BROOKS. Yes; I think this is true. Also, the institutional base grant program of the National Science Foundation has been a tremendously valuable thing in giving the institution funds which can get the younger and lesser known investigators started, give them the few little things they need to get started without having to go back to Washington to ask for funding for a specific project. So this kind of flexibility provided by the institutional base grants is very important in providing just the kind of freewheeling that you are talking about. But still there is a selection process going on within the institution because somebody has to decide who gets supported and who doesn't.

Mr. BROWN. Am I correct in my understanding that a fundamental part of the training of all basic researchers now is how to write proposals so they can get grants?

Dr. BROOKS. Not consciously, at least.

Mr. VIVIAN. Could I make a comment on that? I think one of the problems that the basic researcher finds, in fact, is to know where in the basic university curriculum does he find out how to write proposals for grants. He soon learns.

Dr. BROOKS. Usually within the institution, the graduate students and the postdoctoral fellows and so on essentially receive their support under the umbrella of some more senior faculty member. It is only when they get out with an independent faculty appointment that they are faced with the cold, hard world of reality of seeking support. This support has to be sought whether within the institution or outside the institution.

Mr. VIVIAN. The second part of their experience which they develop within the first 4 or 5 years is to determine which of the Government agencies are located in the Pentagon, which are located on this side of the river, and from which agency they should find support. These things are not taught in the university curriculum, but I am sure they [illegible]

Dr. BROOKS. This is taught by osmosis. I think, Mr. Chairman, I was just in the course of reading the list of criteria for the choice of academic research. [Reading:]

(*a*) The promise of significant scientific results from the project. The evaluation of "promise" implicitly involves the past record of performance of the people who will do the work and their promise of future accomplishment as judged by colleagues or peers. The term "significant" may refer either to intrinsic scientific interest, or to potential applications, or both, but implies some degree of fundamentality and generalizability.

(*b*) The novelty, originality, and uniqueness of the work proposed; the degree to which it breaks new ground, exploits new techniques, or provides a critical test of current theory or understanding.

(*c*) The degree to which the results are likely to influence other work either in the same field or in related or even distant fields.

(*d*) The educational value of the work, based on quality and number of students or other temporary colleagues involved in relation to cost, record of success of past students of the investigator, and the general academic environments in which the work is done.

(*e*) Possible relevance to future applications of interest to responsoring agency. Except in applied-type research this criterion should be given lower priority in academic research, even when supported by mission-oriented agencies than in the case of programmatic or establishment research. I am suggesting that these are the sorts of criteria that ought to be applied either by the committees of peers, the advisory panels and so on that evaluate research proposals, or within the institution by the academic administrators who, in fact, allot funds for research within the institution.

Mr. DADDARIO. How are these criteria being applied by NSF?

Dr. BROOKS. In general I would say these are the criteria that are applied somewhat intuitively, perhaps not explicitly, by NSF panels and, indeed, also by deans and department chairmen in universities. The attempt here really was to try to make explicit for you gentlemen what I think the intuitive or implicit criteria are and that are being applied and I think are properly applied.

The second question you asked, Mr. Chairman, relates to the role of the National Science Foundation as viewed by the individual investigator. To some extent I feel I have already covered this question in the preceding discussion. I would like to stress again the general feeling in the academic community that the National Science Foundation is the agency par excellence which should identify with the interests and the maximum scientific creativity of the individual investigator. Thus, I feel particularly strong that any new ventures on the part of the National Science Foundation should always be carefully evaluated in terms of their effect on the relationship between the National Science Foundation and the individual university scientist. If the National Science Foundation administration becomes too preoccupied with glamorous projects in "big science" or with high prestige applied activities, attention to the needs of the individual investigator may suffer. In general I feel the National Science Foundation should enter programmatic-type research projects only when there is a pretty clear case that they are of such a nature as to extend and support the opportunities available to the university scientific community. Kitt Peak and the National Radio Astronomy Observatory are clearly examples of such activities. I am not saying that university research is the only type of basic research the Government should support but only that it is peculiarly the type of research with which the National Science Foundation should be concerned, and particularly that which pertains to the individual investigator.

There is no question in my mind, also, Mr. Chairman, that the individual scientist prefers the project grant system, with project selection by committees of peers, to all other systems of support. If I have myself occasionally argued for other systems of support, such as institutional grants, it may be partly because of my bias as a university administrator, but also it is my feeling that perhaps the balance has gone a little too far in the direction of purely project support. Nevertheless I would like to make it quite clear that I would never argue that the project support system should not, so to speak, be the baseload of the research support system. The project support systems help the administrator to calibrate his faculty against their peers throughout the country and to reinforce his personal judgments about people in fields remote from his own area of specialization. No academic administrator is possibly competent to judge completely the work of the faculty under his jurisdiction, and if he thinks he can he is exhibiting

a degree of intellectual arrogance with which I have little sympathy. The beauty of our present research support system is that it makes possible an optimum blending of institutional, disciplinary, and personal judgments which is far better than any one of these bases of judgment alone.

There are two other beneficial aspects of the project support system, particularly as used by the National Science Foundation and the National Institutes of Health, which in my mind need emphasis at this time. The first has to do with the coordination of basic research. Almost invariably the individual scientists who serve on study sections of the National Institutes of Health or advisory panels of the National Science Foundation speak of the value of this experience for their own intellectual development, especially in attaining a broader perspective on their own field, and being thoroughly aware in their own work of the work underway in other laboratories. The panel method is a strong influence against parochialism and overspecialization in basic research, and probably one of the more effective ways we have of avoiding undesirable duplication or overlap between researchers. It may, of course, have some tendency to reinforce fashions and to undervalue the maverick or the promising but unusually unconventional young investigator. However, a small proportion of institutional grants can be used to offset this disadvantage. The man who is unappreciated by his own colleagues may be recognized by his peers in his discipline, and the man who is unappreciated by his peers may nevertheless be recognized by his close colleagues.

If we have both methods of recognition and support available within the university I think we will have a better blend than would be possible with either one alone.

An even more important point about project grants awarded on the basis of merit is the recognition they give for outstanding performance, especially in smaller or lesser known institutions. They provide the ideal mechanism by which a capable investigator can be recognized wherever he is, and such recognition often provides an excellent guide to the administrator as to where the real points of strength in his institution lie and where he ought to try to build. Conversely, the fact that even a prestigious scientist can be turned down on a mediocre proposal has a tremendously salutory effect on those who have become complacent with past success and recognition.

You have also raised a question about National Science Foundation statistics. This is a subject that I approach with some trepidation. I think we all agree that research statistics leave something to be desired, yet I would also state without hesitation that the National Science Foundation leads the world in the collection of such statistics. In my recent contacts in Europe through the scientific directorate of the Organization for Economic Cooperation and Development I have been tremendously impressed by the respect and admiration in which Dr. Perlman is held by his opposite numbers in other countries. Dr. Perlman has in the past been responsible for the development of the statistical program, the collection of research statistics in NSF. The trouble with statistics is that the appetite of the policymaker always outruns the menu which the statistical expert is willing to put before him. Always conscious of how easy it is to lie with statistics, the statistical section of the National Science Foundation has been very

reluctant to release or publish numbers for use by people with an inadequate understanding of their limitations. This has often resulted in delays in publication which seem incomprehensible to those of us who do not appreciate the checking and cross-checking which must go into the assembly of valid statistics. Let us not forget that it took more than 30 years to produce reasonable economic statistics for the U.S. economy, and that even today a responsible Government committee can question with some merit the statistics on which our supposed adverse balance-of-payments position are based. Is it any wonder that, in the wisdom of hindsight, some of the National Science Foundation statistics fall short of our best expectations? The problem is not really to criticize the past, but rather to try to learn from our present experience how we may do better in the future.

It seems to me there are two areas in which the National Science Foundation might be able to improve their statistical procedures. First they might make more effective use than they have in the past of studies in depth of relatively small but properly selected samples.

Such studies are in fact beginning. For example, making use of the National Register of Scientific Personnel.

Secondly, I think the planning and statistical groups in the National Science Foundation could make more effective use of the knowledge and experience of the program officers, the people concerned with substantive areas of science. Finally, I would remark that National Science Foundation data collection in the past has both benefited and suffered from being decoupled from the policymaking process. It has benefited in the sense that the lack of strong policy pressures have enabled the statistical groups to develop their system in an orderly and coherent fashion with scrupulous attention to sound methology. It has suffered, on the other hand, from a certain lack of the discipline imposed by the need to find answers to specific policy issues.

In this sense I think the growing complementary roles of the Office of Science and Technology and the National Science Foundation in the formulation and implementation of science policy will serve to strengthen the data collection program of the National Science Foundation by giving it a focus and a policy relevance which was lacking when, essentially, the National Science Foundation had nobody in the Executive Office to talk to. There are already signs that this is taking place, not only as a result of the coupling between the National Science Foundation and the Office of Science and Technology but also because of the interest shown by congressional groups such as this committee in finding quantitative answers to specific policy questions such as geographical distribution of research funds. The policymaking and the data collecting groups have much to learn from each other. Policymakers must learn to appreciate the limitations of statistical data and not draw unjustified conclusions; the data collectors must learn how to design their questions to focus on more specific policy issues and alternatives without overtaxing the system from which the data must be obtained with redundant or unnecessarily detailed questions.

It is often still very difficult to find out from the National Science Foundation statistics what the trends in support of, for example, academic research in specific fields really are. We have no good statistical way of separating programmatic research from academic research or big science from little science. We do not know how to

count the contribution of the big science projects like Brookhaven to the totality of academic research support. The reporting of private and other non-Federal resources going into academic research is 2 to 3 years behind the fact. We know too little about the rising costs of research measured in professional man-years, and what the principal components are in this cost increase. Conversely, although many of us suspect that research productivity measured in results per man-year of effort, has increased rapidly, we have no good tools for measuring this. It is difficult to obtain a clear picture of the significance of research in the total educational enterprise, especially as it varies between disciplines and types of institutions.

Finally I would like to add a few remarks concerning the role of the National Science Foundation in applied science. I know this is something in which your committee has an interest. I find it a complex and difficult question. In general I feel that the National Science Foundation should be cautious about entering applied science areas, and I think it should consider doing so mainly in those areas where the support of applied activities would clearly make an important contribution toward a more balanced advanced training of technologists. Let me amplify.

It is, of course, a commonplace that the universities are the appropriate and logical location for much of the Nation's basic research, especially that having individualistic rather than programmatic character. However, the universities also have an important role to play in the training of engineers, doctors, and other applied scientists. Indeed nearly half of the federally supported research in universities proper is classified as applied, and research is playing an increasing role in the training of engineers and doctors, who must increasingly be "research minded" even to be effective practitioners. Now, whereas the support of research in relation to graduate education in the pure sciences offers no particular policy or educational problems, research in connection with engineering and medical education is much more complicated. The complication is increased by the fact that there are certain basic intellectual disciplines which have been traditionally associated with professional engineering or medicine, even though intellectually they are just as basic, in the sense of being not immediately applicable, as many topics in pure physics and mathematics.

Examples in engineering are communications theory, systems theory, or basic fluid dynamics. These are engineering sciences which can be and are supported under the National Science Foundation's authorization to support basic research.

On the whole these fundamental aspects of engineering have been fairly well supported, at least relative to other fields of basic science and support for them should continue to grow. The basic research support grant is an appropriate mechanism for doing this, although I feel that more use should be made of industrial scientists and engineers on the panels which evaluate such grants supported by the engineering division. However, engineering science is not all of engineering, and the question arises as to what balance of research activity makes for the most suitable environment for the training of graduate engineers, and indeed undergraduate engineers as well, since the orientation and interest of the faculty is largely determined by their research and design activities. This problem of balance between basic and applied

research interests seems to have been reasonably well solved in medical education because the practice of medicine actually takes place within the university complex through the mechanism of the teaching hospital, and through clinical research. However, we have nothing to correspond with the teaching hospital or with clinical teaching and research in engineering and applied science. If a university gets into the business of making commercially useful products or even providing consulting services in competition with private enterprise, there immediately arises a cry of unfair; that is, subsidized, competition. Professor Teller has suggested that large Government-financed installations like the Livermore Laboratory could be used in the training of applied scientists through providing a more complete "real life" engineering environment than is possible on a university campus. This has some merit, but in my opinion falls short of being a real solution of the problem.

In fact, part of the "problem" is that 65 percent of all university engineering research is financed by defense and space agencies, and the absence of corporate support from industry and other Federal agencies has tended to orient both students and faculty away from interest in the problems peculiar to the design of products, processes, and systems where economic and political constraints are of primary importance. Using the Government "big science" laboratories for training purposes will tend to reinforce the bias of engineering education toward the "forced development" Government market, in which economic considerations are secondary. I believe we have here a problem which the National Science Foundation, because of its involvement with graduate education, has to do a good deal of thinking about. Furthermore, I do not believe that the project grant mechanism, which is so suitable for basic research, is as effective for the more applied types of research or for projects in design with economic constraints. Yet I think the National Science Foundation should, in general, stay out of the area of applied research except in cases where extension of its authorization to applied research would clearly contribute directly to its responsibility for the advanced education of technologists.

Thank you, Mr. Chairman.

Mr. Daddario. Thank you, Dr. Brooks.

Mr. Yeager, do you have any questions?

Mr. Yeager. Dr. Brooks, I have two questions in regard to the statistical problem. To your knowledge is the National Science Foundation using adequate, up-to-date instrumentation collecting processes to carry out its responsibilities in the area of data collecting, and, secondly, do you believe that the current ratio of funding within the National Science Foundation's budget is sufficient for this purpose?

Dr. Brooks. To answer your first question, that is an area in which I am rather inexpert; that is, the area of methodology of statistics, and all I can report is the general hearsay that I think on the whole the NSF is using good methodology. On the other hand, that is really just hearsay, and I do not have sufficient expertise in this field to really provide a firsthand professional answer to that question. But generally I think the NSF statistical operation is highly respected from a professional point of view.

The second question, as to whether the funding is adequate, I think is also hard to answer in the sense that from the standpoint of one who

is primarily a consumer of statistics, which I am, my appetite is not satisfied by what the NSF produces. Whether it could be satisfied merely by more funding is a question which is harder to answer. But my feeling is that more funding of the statistical operation of NSF is going to be necessary in the next 5 to 10 years, but whether in fact we have yet a clear enough idea of what exactly needs to be done so that we are really in a position to ask for the funds today and say exactly what we would do with them is a question on which I am considerably more uncertain. One of the objectives of our summer study, which was referred to in Dr. Hornig's testimony, is in fact to take a look at NSF's statistics and Government statistics about research generally from the consumer's point of view, that is to say, from the point of view of the policymaker who needs statistics to make policy recommendations and decisions. So possibly by next fall I will be in a position to give you a little bit more definite answer to that question. That is about the best I can do now.

Mr. YEAGER. Mr. Chairman, I would like to be able to submit any additional questions to Dr. Brooks.

Mr. DADDARIO. Dr. Brooks, we will have other questions. We want to thank you for coming here this morning.[1]

Our next witness is Dr. Shannon. Would you come forward, please?

STATEMENT OF DR. JAMES A. SHANNON, DIRECTOR, NATIONAL INSTITUTES OF HEALTH, ACCOMPANIED BY JOSEPH S. MURTAUGH, CHIEF, OFFICE FOR PROGRAM PLANNING

Dr. SHANNON. Mr. Chairman, may I bring——

Mr. DADDARIO. Yes; I was going to suggest that you have the members of your staff come up.

Dr. SHANNON. This is Mr. Joseph Murtaugh, Chief of our Office of Program Planning, and if we get questions on figures or specifics, with his help I can give you more prompt answers than if I try to trust to my own recollection.

Mr. DADDARIO. Our next witness is Dr. James A. Shannon, who is the Director of the National Institutes of Health. We are pleased to have you here this morning, Dr. Shannon.

Dr. SHANNON. Thank you very much, sir.

Before going into the statement, Mr. Daddario, I would like to call attention to the committee that we have furnished them copies of what is called the "Basic Data Relating to the National Institutes of Health." It includes many statistics relating to the operation of the National Institutes of Health.

I would like to say that my comments, here, will depart in minor ways from that which you have before you because in going over it last night I felt it would go smoother with minor editing.

On page 11 there are two numerical errors that I might correct now. I might say these corrections are bringing statistics up to date from a prior year, and they were only completed yesterday afternoon.

In the last paragraph, the 13 billion becomes 15 billion, and 6 percent becomes 7 percent.

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

Otherwise, Mr. Daddario, I am grateful for your invitation to participate in this review of the National Science Foundation. I will be happy to describe for you the relationships between that organization and the National Institutes of Health, and to give you my views on what the further role of the National Science Foundation should or might be. I particularly value this occasion because I recognize that whatever conclusions are reached here about the present and future role of the National Science Foundation will have an impact on all other science programs, including those of the National Institutes of Health.

The fabric of the National Science Foundation programs cannot be reshaped without setting up new lines of force, that—for better or worse—will affect the ability of Federal agencies to accomplish space, health, defense, and other missions requiring a broad scientific base. Nor can one ignore the possible impact upon our national structure for the support and advancement of science, as the concept and functions of the National Science Foundation change. In a very real sense the National Science Foundation occupies a central position in the structure of our Nation's science support and science advancement programs. To the extent that one redefines the characteristics of this central agency, then one must look also to the total Federal science structure to determine what further modifications will have been made necessary.

A second reason for wanting to talk to you is that in my years of administering health-oriented programs that nevertheless touch and interrelate with NSF at innumerable points, I have formulated some personal but quite definite opinions about what the role of the National Science Foundation in science should be. I will confess at once that you will find nothing original or startling in my views. Others have advanced the concepts earlier—and doubtless more eloquently—than I. My recommendations merely reiterate those you will already have heard. But the perspective—or, if you will, the bias—from which I speak will be very clear to you; and the length of that personal perspective (some 10 years during which the National Institutes of Health and the National Science Foundation have both had their maximum growth rate so far) may add at least an element of interest for you.

What I propose to do is as follows: I will first try to capsulize for you the nature of the present NIH activities, how they got that way, and how—through time—they have interrelated with programs and responsibilities of the National Science Foundation. I will also describe several joint National Science Foundation-National Institutes of Health efforts in common problem solving. I will then discuss my view of the present role of National Science Foundation in science and science education, and what I feel are important considerations relating to the future.

The National Institutes of Health has, as its primary mission, the understanding of disease, behavior, and the biological requirements for health. In the furtherance of this mission, NIH has come to play a major role in the support of research in institutions of higher education in our country. Thus it now has an indirect though major role in strengthening graduate education as such and in adding to the vigor of the institutions which largely contain these research programs.

From the beginning it was recognized that effective support for research carries with it the obligation to enlarge the resource base for continued growth in the future. As a consequence, NIH programs have provided fellowships, have strengthened the structure of graduate education in health-related fields, have provided stable support for faculty expansion, and have stimulated the construction of health research facilities through a matching grant program. This basic spectrum of biomedical research and research-related activities has drawn the National Institutes of Health into close and increasingly fruitful relationships with educational institutions. We have become increasingly aware of the capabilities of Federal programs (1) to support research and, at the same time, to strengthen rather than weaken the educational enterprise, and (2) to broaden the Nation's base of biomedical excellence in all regions of the country.

Some comment on the background of this activity may be helpful in understanding the character of present NIH involvement in scientific activities. To shorten this story I will utilize 3 key years: 1945, 1950, and 1965.

In 1945, as World War II ended, the creation of the National Science Foundation was still 5 years away, though Vannevar Bush and others were urging the need for such an agency. In that same year, NIH was in its 59th year as the research arm of the Public Health Service. Essentially, then as now, NIH was a health agency using science as a means to accomplish its objectives.

The basic authority for NIH programs derives from the statutory responsibility of the Surgeon General of the Public Health Service for the conduct and support of research and investigations related to the diseases and impairments of man and other health problems. The general authorization for this purpose appears in section 301 of the Public Health Service Act. In 1945, however, the tangible attributes of NIH were those of a small in-house Federal laboratory. Less than 6 percent of its funds went to support university scientists, and its total budget was less than $3 million.

But in the circumstances of that year—and especially what had grown out of the war years immediately preceding—were all of the essentials for a vast buildup in Federal science support programs. At least in tentative form, the pattern for future NIH expansion was also present:

There was both the identification of major medical problems and an appreciation that the then current state of the art required a broad expansion of basic science for their solution.

There was also clear evidence of a successful wartime partnership between Government and university science in concentrating scientific effort in needed areas.

There was the effective policy and administrative framework for implementing this partnership that the Office of Scientific Research and Development had worked out.

The National Cancer Institute, added to NIH in 1937, set the pattern of later expansion through creation of separate disease-oriented Institutes.

The Public Health Service Act of 1944 gave broad authority for grant support of extramural research projects.

Finally, the 1946 transfer to NIH of the residual OSRD university contracts in the medical sciences constituted the effective beginning of NIH's present-day broadly based extramural research support program.

By 1950, however, a considerable shift had taken place on the national science scene. In that year, in which creation of the National Science Foundation was authorized by Congress, major research support programs of the AEC and Office of Naval Research were well underway. Seven of the nine research Institutes which comprise the present-day National Institutes of Health had been authorized and their programs launched. In 1950, NIH spent $28 million for research—roughly half going for support of research through grants to academic and research institutions throughout the country. NIH training grants programs were then in their third year; and NIH appropriations for 1950 included $6.4 million for these grants, plus $1.4 million for fellowships.

Thus, by the time the legislative authorization for the National Science Foundation had been completed by Congress, the Federal Government was already heavily involved in the support of academic sciences through the postwar development of the mission-oriented Federal agencies. By reason of this somewhat accidental set of circumstances, the basic pattern was forged for the Federal engagement with science in this country.

Since 1950 NIH appropriations have grown steadily until they now (1965) total slightly more than $1 billion. Although the intramural research activities on the Bethesda campus have grown steadily, the extramural programs have expanded at a much more rapid rate, with the increases being particularly striking during the past decade. Expenditures through extramural programs for research, training, and construction grants now account for nine-tenths of the NIH dollar. As a consequence of this progressive and rapid growth, NIH funds now cover 40 percent of total national expenditures for biomedical and health-related research; and also more than one-third of Federal research funds made available to institutions of higher education. Thus at the present time NIH has a substantial investment in university research, and, therefore, a basic concern with their capabilities for productive research as well as for their future growth.

This extensive NIH involvement with academic science and its institutions—though NIH is not primarily a science agency—does not make NIH unique. This, in fact, has become the hallmark of this country's engagement with science at the Federal level. In contrast with the pattern in a number of major countries—where the support of science is approached directly and as a primary consideration—the advancement of basic science in the United States has been in very large part the derivative of national efforts to achieve nonscientific goals: in agriculture, in national defense, in communications, in health, and in other areas. Though there is room to argue the wisdom of this pattern, one cannot say that the results have been bad. For example, one may speculate—with some confidence—that the scope, the magnitude, and the general excellence of academic science is undoubtedly greater today—as a consequence of efforts directed toward national objectives in the areas of health, defense, and space exploration, et

cetera—than could be expected on the basis of seeking support for science primarily for its own sake. There are many strengths in this situation and I believe this will continue to be the pattern for some time to come. However, there are problems of overall balance across fields of science; there is also the need to advance science education generally, and to assure the resources and development of institutions essential to that advancement. These circumstances make critical the need for a total Federal pattern within which academic science as a whole can be dealt with adequately. In this setting the National Science Foundation has a crucial role.

I should like to take a moment at this point to review for the committee the nature and extent of specific NIH–NSF relationships.

In the development of its programs, NIH has worked continuously and closely with NSF. Collaboration has extended to specific scientific studies; to working out generally comparable terms and conditions of support for research, training, fellowship, and facilities programs in similar settings. The two agencies employ basically the same concepts in respect to the peer group review system for academically based research. There is now a growing concern for coordinating activities and programs which focus upon the same institutions.

I would like to cite a few instances of this cooperation: In the field of research and training grants, the executive secretaries of the various NIH study sections and training committee panels maintain close informal contact with program officials of NSF in coordinating action upon proposals from the same investigators and in areas of common interest to avoid inadvertent duplications. Informal discussions of applications received at one or the other of the two agencies which fall outside of the recipient's support area or interest are referred to the other agency for possible funding. As an example of cooperation in more specific programs and program areas, NIH is included in the interagency chemistry representatives, a group that meets twice a year under the auspices of NSF to discuss common problems in the support of chemistry.

In addition, representatives of NSF are invited to attend all NIH National Advisory Council meetings, and indeed, they do attend.

Mr. Daddario. Could you go into that informal contact and informal discussions a little more thoroughly? How do you choose the people; what is the nature of the contact; who controls it, and does it start at the top or does the informal discussion occur between the same levels at each institution?

Dr. Shannon. I would say it occurs really at three levels. My office has quite intimate contact with Dr. Haworth's office, even to the extent that each year we invite their top staff to discuss with our top staff, or make presentations to our top staff of the generalties of their new programs. There is recurring contact which does not need formalization in terms of a committee structure, particularly with Dr. Haworth, Dr. Wilson, and Dr. Perlman. Dr. Perlman is in the statistical area for NSF, as Mr. Murtaugh's group is for our area. I will come to that a little later.

On the intermediate level there are discussions between Institutes staff and comparable divisions within NSF on the development of specific programs. For example, we are both concerned with develop-

ment of programs utilizing computer technology or expanding computer science. On our side, this is handled by the Institute of General Medical Sciences. I can't recall specifically what the NSF group is called.

There is such intimate contact here in terms of individual proposals that we know precisely what NSF is funding, they know precisely what we are funding, and in a variety of instances there is joint funding.

Then, on the working level, we actually have in some of our technical groups, not just liaison representatives of the NSF, but actually some of the NSF staff as members on our technical committees. I have in mind particularly the Advisory Committee of our Office of International Research, where the behavioral sciences are represented by a staff member of NSF. At still a lower level there is such constant interchange between members of our Division of Research Grants and their counterpart in NSF that to try to formalize this with a committee would be to introduce red tape that would impair the effectiveness of the interchange.

On administrative matters there are joint committees on the terms and conditions of grants, on fellowships, on the handling of overhead—things of that sort. In facilities construction, one of the senior NSF staff members actually sits as a nonvoting member of our Research Facilities Construction Advisory Council.

For general research support grants from the beginning, there has been an intimate and continuing interchange that relates NSF and its objectives to us and to our objectives. Indeed, the general research support grant and its possible extension to the universities was the subject of continuing discussions by a Saturday morning group that was started by Dr. Wiesner and operated over a 6 to 8 month period before general decisions were reached. Here again, it was not only NSF and ourselves that were participants but also Space, AEC, DOD, and the Office of Education; in other words, all of the elements that relate one to the other in framing the generalities of the relationships between the Federal establishment and the university. What I can do, Mr. Daddario, if you would like, is to give you a listing of the formal NIH-NSF relationships in terms of committees; but I would feel that the extraordinary degree of contact between our operation and Dr. Haworth's operation is characterized more by this interdigitation by staff members at all levels than by formal committees.

Mr. Daddario. We understand from the testimony here that the informal relationship between the agencies is far better, even though it is necessary to have a certain amount of formal relationship. I would appreciate it if you could supply us for the record with the formal relationships that exist, and a further explanation of the informal relationships, although you have been quite clear as to why you believe they are important.

As you discuss your relationship to the National Science Foundation, is there anything which indicates that there should be an even closer relationship because of the nature of the work done?

Dr. Shannon. I am going to touch on certain aspects of this as we go on with the statement, but we would be very glad to provide an additional statement.

(The information requested is as follows:)

STATEMENT OF FORMAL RELATIONSHIPS BETWEEN NSF AND NIH; FURTHER EXPLANATION OF INFORMAL RELATIONSHIPS AND THEIR IMPORTANCE; OPPORTUNITIES FOR FURTHER CLOSER RELATIONSHIPS.

Formal relationships.—(1) National Science Foundation representatives attending NIH Advisory Council meetings:

Council	Staff member	Representative capacity
National Institute of Allergy and Infectious Diseases	David B. Tyler	Liaison.
National Advisory Arthritis and Metabolic Diseases	do	Do.
National Advisory Cancer	do	Do.
National Advisory Child Health and Human Development.	Philip Grant	Do.
National Advisory Dental	David B. Tyler	Do.
National Advisory Heart	do	Do.
National Advisory Neurological Diseases and Blindness	do	Do.
National Institute of Mental Health	(Mrs.) Bertha Rubenstein	Do.
National Institute of General Medical Sciences	Fred Hansing	Do.

(2) Also, formal relationship between the National Science Foundation and the National Health Research Facilities Council (advisory to the NIH Division of Research Facilities and Resources) is specified by section 703(a) of the Public Health Service Act. This section reads in part: "There is hereby established in the Public Health Service a National Advisory Council on Health Research Facilities, consisting of the Surgeon General of the Public Health Service, who shall be Chairman, and *an official of the National Science Foundation designated by the National Science Board, who shall be ex officio members,* and * * *." [Italic supplied.] The National Science Foundation has designated Dr. Howard E. Page as its current ex officio member, with Dr. Harve Carlson as alternate.

Other formal relationships.—The NIH and NSF on occasion enter into formal arrangements for the joint support of research projects, research facilities and other scientific endeavors of mutual interest. A complete list of joint funding relationships between NSF and the Division of Research Facilities and Resources is presented elsewhere in records of these hearings.

Advisory Committee on Animal Resources and General Research Support Committee of Division of Research Facilities and Resources.	(1)	(1)

[1] Invite NSF program liaison as necessary.

(2) *Interactions between study section officers (NIH) and program directors (NSF).*—The executive secretaries of the various study sections of the Division of Research Grants and of the training committee panels of NIH maintain close contacts informally by telephone and personal meetings with specific program directors of NSF in cross-checking on details of applications received in common by both agencies to insure that duplicate applications are not jointly funded. Informal discussion of applications received in common by both agencies which fall outside of one support area or interest are referred to the other agency for possible funding interest. This is a standing practice of frequent occurrence.

While the Division of Research Grants (NIH) does not have formally appointed observers from NSF attending its 52 separate study section meetings, informal observers are present at meetings of selected study sections when necessary as determined by common interest of NIH and NSF project reviewing officers. For example, NSF liaison observers are routinely invited and attend meetings of the cell biology, genetics, human embryology and development, and biophysics and biophysical chemistry study sections. Arrangements for attendance of NSF observers in other study sections are made when appropriate because of program considerations or matters involving joint interest on particular projects under review. Similarly, executive secretaries of the NIH study sections listed above are notified of NSF panel meetings and have standing invitations to attend as observers. Attendance depends upon time available from office duties and the nature of topics and awards to be discussed. It has been found that the arrangements made informally based upon mutually determined needs of the officials involved are administratively worthwhile. Questions concerning grant policies at each agency are answered. Each officer is kept informed concerning what the other's agency is tending to support, without influencing the review group in the scientific evaluation of either set of applications.

CONCLUSIONS

At present it is considered that the informal arrangements, based upon mutually recognized common interests, are working well and fruitfully. Formalizing the arrangements would not substantially aid the process. Requiring official attendance at times when discussions have little common interest would unnecessarily hamper program officials of both NSF and NIH in carrying out the full schedule of their duties.

It could be recommended that one senior scientist administrator in NIH be given the responsibility for liaison activities between NIH and NSF, to attend meetings (on invitation) of the National Science Board, NSF, and regularly attend meetings of the appropriate NSF advisory group that will be taking the place of the NSF Divisional Committee for Biological and Medical Sciences (recently disestablished). Such a person could serve as a knowledgeable contact source of information within NIH on NSF programs and developments and similarly answer NSF questions on NIH programs. The NIH and NSF should establish mutual agreement on the role and responsibilities of the proposed liaison officer.

Dr. SHANNON. I would say informally, at this point in time, that there is purposeful overlap in these programs in order to avoid inadvertent gaps in some areas. This is not overlap of an inadvertent nature, and certainly not duplication in the sense that carries an unfortunate administrative connotation. We feel that we avoid inadvertent overlap through the process of joint decisionmaking in many cases, common support of programs, and things of that general sort.

Mr. DADDARIO. It may be helpful if you could give us some examples of how you decide that you should have common support for programing. You stress the idea that you each know what the other is doing in the funding of programs, and that you move on some occasions to joint programing. How you move from the one to the other?

Dr. SHANNON. I can give you two examples, now, if you would like. We felt a very great need to stimulate computer science to the point where more suitable computer software was available to the biomedical sciences as increasing use of computers was made for compu-

tational purposes; for the development of model systems and the like; or the simple handling of complicated data. In the Lincoln Laboratory we had supported the development and actual manufacture of about a dozen small computers that are called Linc computers. These are individual laboratory computers. We became sufficiently interested in the possibility of expanding this activity into new areas that we approached MIT to discuss with them whether they would be willing to establish a group for computer sciences for these purposes, making use of the competencies that were available in the Lincoln Laboratory which is run as an independent subsidiary of MIT.

In doing this, we immediately involved NSF, and conversations from the beginning included the two agencies. We had the dominant interest, and we paid the dominant part of the cost; but there was participation with NSF in that total activity.

Again in the area of science information, for which NSF has broad responsibilities, NIH and NSF have collaborated on chemical documentation problems. NIH's interest is this: the biomedical sciences are totally dependent upon the development of a more adequate information system to handle the interrelationships of chemical structure and biological activity. Now the Chemical Abstracts Service is a subsidiary of the American Chemical Society. It runs what is accepted as the best abstracting service in the country today—one on which all chemists and biologists have very broad dependence. In discussions with this organization about 2 years ago, NIH asked them to undertake a feasibility study on the possibility of developing an alerting system for this type of chemical-biological information. The result was a special abstracting publication called CBAC. Meanwhile, NSF's interest in this general area (also that of the National Academy of Sciences) was in the feasibility of coding all chemical compounds based upon present hardware and present chemical knowledge. For this purpose, the Chemical Abstracts Service had developed a workable system: they put out a journal (Chemical Abstracts). But last year, they reached the conclusion that because of the volume of material becoming available, the Chemical Abstracts Journal would not be publishable in 5 to 7 years. They had to move over to a computer-based system. Before doing this, though, they had to develop a universal system for the coding of all chemical compounds (of which there are somewhere between 2 and 3 million), and a series of subject registers which might relate structure to biological activity.

When we learned of this we asked Chemical Abstracts Service to develop an overall proposal of what they would like to do in terms of National Chemical information needs. We took their proposal to the Office of Science and Technology, saying that we felt this was a problem that went far beyond us. We were willing to put up a substantial amount of money, but we felt the other large supporters of chemical information systems (NSF and DOD) should take or share the lead in a program that would satisfy our needs as well as theirs. OST adopted this position and the result is a program now being run by NSF on funds from NSF, NIH and DOD. We did the preliminary work within my office, developed the elements of a program, and turned over our proposals to OST as the logical organization to pull the Federal agencies together and determine how the program

should be handled. It is being handled by NSF in line with NSF's general responsibilities for the handling of scientific information. This is the type of relationship that has developed between our operation and NSF, which depends more upon intimate knowledge of each other's programs and intimate contact with people than on formal committee structure.

The Division of Research Facilities and Resources at NIH has continuing interchange between its facilities program officials and their counterparts at NSF. This interchange is particularly active when there is need to work out details of joint funding for the construction of building and facilities at particular universities.

In line with your questioning, Mr. Daddario, we can give you a list of joint funding arrangements.

Dr. SHANNON. A representative of NSF sits as a nonvoting member with the National Advisory Council on Health Research Facilities when construction proposals are reviewed.

In fellowships, semiannual conferences of Federal fellowships program administrators are held under NSF auspices. At these meetings, common policies on stipend and support levels are nego-

tiated; there are also informal discussions and agreements on delineation of respective scientific spheres, on problems of projections, and so forth.

In the development of resources data, NSF surveys have been expanded to provide the level of detail, especially for the biosciences, needed by NIH. In other instances, such as the 1960 Survey of Foundations and this year's Survey of Research Institutes, the Science Foundation has added a separate sheet for medical and health-related activities; this is made available to the National Institutes of Health for analysis and publication.

Also, the National Science Foundation maintains the National Register of Scientists and Engineers through the use of biennial questionnaires. NSF has made available to NIH decks of IBM cards from this roster for more detailed analysis in fields of specific concern. NSF has also provided NIH with a deck of IBM cards covering the responses of institutions to its Survey of Research Facility Requirements, 1962–70.

NSF and NIH have jointly financed studies and surveys relating to scientific manpower, graduate education, and university activities of common concern and interest. These illustrate only a few of the many continuing relationships that exist between NSF and NIH. This interchange and common action have been cordial, productive, and mutually contributory to the advancement of our respective programs.

From the perspective of an agency supporting science to accomplish nonscientific ends—the eradication of disease—one might pose the question: What should the future NSF role be in the support of science?

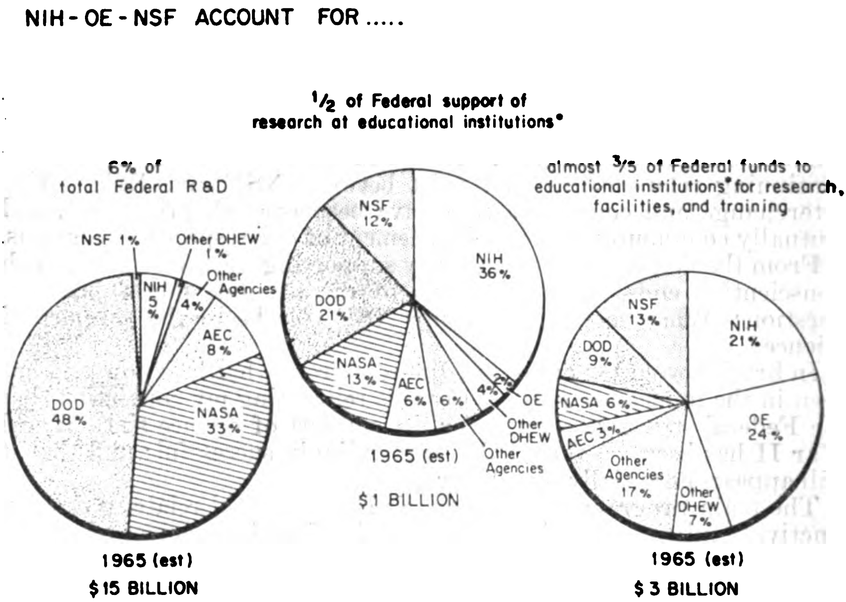
In brief, I would say: not too different from what it is now and has been in the immediate past. I say this reiterating my conviction that the Federal structure erected for the support of science since World War II has been, on the whole, outstandingly successful; and that it still appears essentially sound to me.

The main program strengths of NSF then would relate to the distinctive, explicit, and primary concern for the advancement of science assigned to NSF. These are: the support of basic science research, the enlargement of scientific and technical manpower, advancing the institutional structure and resources for science and science education, and the doing of these things without the restriction of a substantive mission. I believe that NSF should be so funded that it can assure world leadership for the United States in the future course of scientific development. Importantly, this would mean that NSF should be funded generously to fill meaningful gaps and deficiencies in the science structure left by mission-oriented agencies such as AEC, NASA, Defense, NIH, and so forth. It should not, however, be limited to this role. The NSF function in measuring and analyzing the quantitative and economic characteristics of science and its resources is basic to formulation of programs and policy. Its concern with the crucial role of science, as a national resource, as an instrument for strengthening international relations and—in a quite literal sense—as the determinant of the destiny of man, must be reflected in the scope and magnitude of its activities. These views, you will note, are generally in accord with the consensus on the functional concept and "balance wheel" role for

NSF advanced in the recent study by the National Academy of Sciences.

I trust that in what I have said above I will not be understood to be urging adherence to status quo precepts for their own sake, or because they are generally favorable for a particular agency. On the contrary, it is the flexibility and capaciousness of the present science structure that I value and would like to see carried into the future.

As a final consideration I would like to emphasize an important point relating to the present distribution of Federal support for science and related activities which should stand clear to the committee and the Congress in the further pursuit of this inquiry. For this purpose we have prepared a chart. This chart (fig. 1) portrays three aspects of Federal expenditures for research and development:



*Excludes university-managed Federal contract research centers.

SOURCES: Office of Education, National Science Foundation, National Institutes of Health.

RAB-OPP-NIH 7/65

FIGURE 1

The first pie diagram shows the proportionate distribution of total Federal expenditures of $15 billion for research and development amongst the major Federal agencies involved. The inclusion of the large-scale expenditures for hardware development contributes to the dominant positions of the Department of Defense, NASA and AEC in this presentation. NSF, NIH, and other DHEW agencies whose programs are centered in research rather than development account for only 7 percent of the total Federal research and development activity.

In the second pie diagram the focus shifts to that portion of Federal R. & D. expenditure, approximately $1 billion, comprising Federal support of research in educational institutions. This is the area of support for academic science and encompasses the major portion of

the total national support for basic research. In this context the proportionate roles of the several Federal agencies shift markedly: the National Institutes of Health—constituting 36 percent of total—emerges as the Federal agency supporting the largest proportion of academic research.

NIH, together with NSF, the Office of Education, and other HEW agencies accounts for over one-half of all Federal support for research in academic institutions. The critical role of NIH and NSF in sustaining academic science is apparent.

In the third pie diagram, the focus on educational institutions continues. However, the data not only show support for research in such institutions, but Federal expenditures for training and for construction of teaching and research facilities as well. This expenditure is estimated at $3 billion in fiscal year 1965. Here the role of the Office of Education in the support of training and the construction of academic facilities shows its effect. Altogether the activities of NSF, NIH, OE, and other HEW agencies comprise 65 percent of the Federal funds going to educational institutions for training, for research, and for construction. Given the growing dependence of institutions of higher learning upon Federal support, the crucial role played by NIH, NSF, and the OE in the destiny of the national structure for higher education is dramatically emphasized by these data.

The relevance to this committee of the concentration of Federal support for academic sciences in the program of these three agencies is, I think, obvious. There is, moreover, a set of considerations which I should like to depict briefly since they are integral to your concern with the National Science Foundation:

1. Although the Office of Education occupies a dominant position in respect to the support of training and the construction of educational facilities, its role in the support of the substance of science remains minor as shown by the second pie diagram.

2. The NIH and NSF occupy a critical position in respect to the support of university research, particularly in face of declining DOD expenditures in these areas.

3. The further growth of NIH as an agency concerned with the solution of major disease problems will involve positive efforts to provide movement along two fronts:

(*a*) An increased extension of the advances in basic science and technology to the specific problems of the major diseases through applied and developmental activities.

(*b*) Broad efforts to bring the physical, behavioral, and mathematical sciences into more intimate involvement with the biomedical sciences in the provision of stable base for this applied effort. Great care will be required of administrators and legislators in the furtherance of this dual process to avoid distorting an existing balance between that which is fundamental and that which is applied, or bringing one into conflict with the other.

4. Somewhat comparable problems will be presented to NSF. National circumstances will require continuing involvement of NSF in the direction and management of large-scale science projects such as Mohole, radioastronomy, and weather modification. This is sound in terms of the importance of these projects for science and science edu-

cation generally. But it will continue to be sound only if NSF can direct ever-increasing resources to its pivotal role and imperative function of providing for the stability, vigor, and growth of academic science.

Mr. DADDARIO. Do you mean that unless NSF can get the funds to conduct such large projects as Mohole and to do these other things, that it ought not get involved?

Dr. SHANNON. I think that the imperative for the National Science Foundation is to provide a stable base for basic research; if it should turn now to engagement in these large national enterprises, which are essential—but for reasons secondary to NSF's primary mission—I think this would do the country a disservice. If I may be a little critical of the budget action this year——

Mr. DADDARIO. Go right ahead.

Dr. SHANNON. We find support for undifferentiated science is very little different than it was last year, although some of the specialized programs have been expanded. To me this does not make good sense, sir. Quite frankly, this makes our job harder; and one never wants to make his own job any harder than it has to be. I would say the keystone of NSF programs must be support of the undifferentiated, fundamental research which is essential for the health and vigor of our higher educational enterprise.

Mr. DADDARIO. That is the main task for NSF. It ought to be attracted to other tasks only in relation to the funding available to carry out this primary task?

Dr. SHANNON. Yes, sir. I think that there is no doubt that Mohole, radioastronomy, and ground-based optical astronomy are essential projects on the national science scene. They are particularly so for postdoctoral training and the development of scientists that cannot be created at individual universities. But it would be a disservice for the National Science Foundation to accumulate a series of these programs—and more particularly, to go into the applied area, as I know is under consideration, at the cost of limiting its ability to expand in its pivotal role. I think these national resources—and certain concepts in relation to applied work—are important in themselves, but not if they weaken the integrity of our science establishment. This basically depends upon the central role of the university and its ability to provide the opportunity for scientists to conduct research of their own selection, with the concept of excellence determining who shall be supported and to what extent.

Mr. DADDARIO. You have already touched on the critical position of NSF and NIH in regard to the support of university research, particularly as there is a decline in DOD's expenditures in this area. NSF will have an expanding role, perhaps to take up the slack, but if it gets itself involved in other areas at the same time, a declining effect within NSF could be created if it is not careful.

Dr. SHANNON. There are two other things, too, that have a very direct bearing on this. That is, the total cost of these large national efforts is not yet on the books. Once begun, they will of necessity increase.

Mr. DADDARIO. I do not know of any which decrease.

Dr. SHANNON. I haven't seen the budget for Mohole, for example; and I don't know the details of the program. I would guess, though,

that the annual expenditure over the next 5 years will increase fairly dramatically. Certainly this is going to be the case with radio-astronomy. So one looks forward to a mandatory increase in these areas where one has made a national commitment. But the ability to use these resources effectively—and the ability to bring these national programs home with highly productive results—will really depend largely on the extent to which the academic base can be strengthened.

Also in this year's budget, NSF was encouraged to go forward in their science development program, but at the same time, their support for undifferentiated projects was cut back. I think this is an inconsistent action. Unless there is assurance of broader support for this agency, then there is no point in stimulating large efforts just to get more people to compete for less funds. I think these are some of the concepts that one must consider very seriously in viewing the future of agencies such as NSF. Quite frankly, Mr. Daddario, I am concerned that there has not been adequate attention to the long-range consequences of some of the money decisions.

Mr. DADDARIO. Your concern is that the cost of these projects will go up at a greater percentage rate than the support that NSF will get?

Dr. SHANNON. Yes, sir.

Mr. CONABLE. This is one of our difficulties with Government in general. We have had a tendency to consider the resources as unlimited and therefore to accept desirable programs without considering their impact on each other. We have to look at the long-term view or we will be in trouble eventually, and probably in an area of mutual interference.

Dr. SHANNON. I realize your problem, sir, and as I have told our appropriation committee repeatedly, I wouldn't like to be in their position. They have to make some very rough decisions. I would emphasize to you that the agencies that support or relate themselves to academic science spend only 7 percent of the total R. & D. funds. Now I hate to erode other people's budgets for self-seeking purposes, but I would point out that if you take these other agencies and reduce them by 1 percent, I don't think that they would be particularly harmed. But this would result in a 14-percent increase in those agencies that specifically relate to the intellectual base we are trying to build. Indeed, 20 years from now, we will be able to continue to do exciting new work in space, in defense, and in medicine only if during the intervening period we produce the group of highly productive imaginative scientists we will need. The disparity between support for innovation research—whether done in a Federal laboratory or an academic environment—and the tremendous cost for harware development and the like, does give me some pause. I think in the report, Mr. Daddario, that the National Academy of Sciences prepared for this committee, this point was made by a number of people. One concern with our form of government is that within the Congress and the executive branch we tend to fragment science to an inordinate degree, whereas science in the doing is not so fragmented. This is one of the reasons why I was so delighted, Mr. Daddario, to meet with this committee and to express some of these views. Too frequently we at NIH and our science counterparts in other agencies meet year after year with the same congressional groups, who understand our

programs but do not have the opportunity to look at science programs across the board.

I could become very emotional about some of my comments. They stem from my conviction that the last hundred years has brought the United States to the position that it is now in, primarily through the intelligent exploitation of national resources. I think, on the other hand, that where we will be at the end of the next 50 years will depend more on how well we exploit our intellectual resources than on any other single thing.

Because of this conviction, I become troubled when certain things don't happen the way one feels might be optimum. It is this thought that leads me to these expressions of fairly deep concern.

Mr. DADDARIO. We are pleased to have them, Dr. Shannon, and I know they are going to be helpful to us.

Dr. SHANNON. These comments I think have defined the essential areas of relationship between the two agencies—which although quite different in origin, purpose, and role—have been able to accommodate the development of their programs in a mutually reinforcing manner. As I noted at the beginning of these remarks, modification in one agency vitally affects the other.

These are matters which will benefit, I know, from the constructive deliberations of this committee.

I want to thank you for the opportunity which you have provided me to contribute to this important examination of an agency which in 15 short years has become indispensable to the national welfare. I should be pleased to answer any questions, sir.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Doctor, an area of funding which seems to have considerable overlap between the NIH and the NSF, is basic research in the biological sciences. This accounts for roughly a third of the National Science Foundation's activities, and for a much larger proportion of yours. In the area of physical science there is not so much overlap, although there may be. Is this a problem? Have you means or techniques by which, to some extent, you have agreed on a program for mutually supporting funding? Have you tried to establish criteria or standards to determine which will be done by your organization or by the NSF?

Dr. SHANNON. I think there is surprisingly little overlap in the main area of truly mutual funding; that is, the individual research project. There may be a substantial number of individual proposals which could go either place, but the dollar volume of these would be a small portion of the total program. I would say that there is no really large expenditure in terms of a large program that doesn't receive at least the informal joint consideration by both agencies. We would be delighted to submit for the committee an analysis of this area of overlap and try to indicate to you what are the qualitative characteristics generally of those things that we support. We can work with NSF on this and let them indicate for themselves the qualitative character of what they support in this area of potential overlap.

The most obvious interrelation here is the referral from one agency to the other of projects that are considered not suitable for the referring agency but suitable for the other agency. Also, there are quite a few instances of almost identical proposals being sent to both agen-

cies, because the proposer himself doesn't know which program his project will fit into best. These call for central (really joint) decisions on which agency should review the proposal.

Mr. Murtaugh points out a fact that would be of interest to you. In our aggregate funds, 50 percent go into so-called professional schools related to the health professions, and 25 percent to universities, primarily colleges of arts and science and engineering. NSF has its primary "clientele" in universities outside the health professional schools. I can go further and say that apart from these health professional schools, NIH's major preoccupation in universities would be in areas of biophysics, biology, in certain departments of veterinary schools, and so forth. When these specific NIH interests are pulled out, there is quite a different mix supported by NIH within the university group as compared to NSF. We will try to develop——

Mr. Brown. I am satisfied that we are not getting duplication. I was looking for some broad criteria which distinguish that portion of the NSF budget which is concerned with biological science with yours. The remarks you have just made give me some indication of that.

You made some passing reference to the behavioral sciences in connection with NSF. Could you give me a little more indication of what you define to be the behavioral sciences and the nature of NIH's relationship to them?

Dr. Shannon. Yes, sir. We have been intimately involved with the behavioral sciences and indeed, until the development of the National Science Foundation we were the only agency that supported any work in the behavioral sciences. This interest grew of our activities in the field of mental health—the effort to develop an understanding of the behavioral bases for aberrations from the normal. We are concerned with general fields of anthropology and psychology—cultural anthropology in particular; and psychology, from both the standpoint of understanding certain of the mechanics of thought, and of developing suitable testing procedures for change in mental state. But it became obvious more than 20 years ago that the behavioral sciences input into medicine went substantially beyond the problems of mental health. Indeed, most of us at some time in our life have somatic reflections of emotional disturbances of one kind or another, and this becomes the basis of so-called psychosomatic medicine.

The Mental Health Institute, which was created as a research institute in 1946, had a behavioral science program that went beyond its needs for its understanding of specific mental illnesses. For the better part of 10 years it helped to evolve broad competence in our universities in areas tangential to, but nonetheless contributory to, an understanding of mental illness—such as the problems of juvenile delinquency. But even so we felt that our support for the behavioral sciences was developing too limited a pattern. So we asked our Division of General Medical Sciences to engage itself in a broader, noncategorical approach, to the behavioral sciences, with the objective of pointing up the various areas which might have contributions to make to fields of medicine. We were especially interested in aspects of these sciences permitting us to understand better the emotional and intellectual development of the child.

You will appreciate that it becomes quite impossible to discuss mental retardation unless one has a basis for understanding what is nor-

mal. Also, it becomes impossible to study the normal unless one realizes that at one end you have the exceptional child, and at the other end, the retarded child. So, when we were asked by President Kennedy to consider setting up an Institute of Child Health—with mental retardation to be a major concern—we countered by saying that we felt there was not an area of child health, per se, that made sense to us, but rather, we would like to approach the problem in terms of human development. As a counterproposal we said we would like to organize an Institute of Human Development.

Without going further into the why's or wherefore's, we now have an Institute of Child Health and Human Development, and I think this is fine. But when we talk about development, we talk about emotional, intellectual, and biological development of the child. And when we talk about emotional or intellectual development, we are right across the border into the behavioral sciences. This new Institute is now in the third year. It is just beginning to engage itself seriously in such problems as development of intellectual capabilities, the emotional reactions of humans, and so forth. Basically I would say NIH is a health agency rather than a disease agency. Until we know more about the normal—the factors that contribute to normalcy, and the factors that relate to the development of speech and educational ability, also the emotional response of a child during the rapidly changing years from 3 to 5—then I don't think we are in a position to interpret disease manifestations in those systems. In this sense, we now have gone far into the behavioral sciences as compared to the early attempt to find a base for the manic depressive personality or the schizoid and things of that general sort. This involves us and will involve us increasingly with the university.

Mr. Brown. Didn't this lead to a further expansion of what you might call the human environment or environmental science in which you will reach the conclusions that behavioral manifestations may stem from economic circumstances or from cultural situations?

Dr. Shannon. We are already into that, sir, at the present time because mental retardation is known to be due more to social deprivations than any other single cause. I don't think we will have to do anything about solving the underlying social problems, but will have to define the circumstances in which social deprivation contributes to mental retardation, and find the best ways of handling the child who has been retarded.

Mr. Brown. I wish in addition to identifying the problem you could identify the solution, but I recognize this may not be appropriate for the National Institutes of Health. I am concerned with the extent to which your resources are now being devoted to identification of the behavioral sciences and environmental conditions, because I think they are closely related and deeply involved in our health problems today.

Dr. Shannon. I will give you another area where the health problem is equally involved with socioeconomic circumstances; and there are medical, biological and behavioral elements: the area of aging. If we were able to apply all the knowledge we have at the present time to the problem of aging, we could greatly diminish its impact as a national problem. But the relevant solutions are more in the socioeconomic than strictly the medical field.

I think it is NIH's responsibility to attempt to define what are the behavioral and biological characteristics of the aging process and what are the inputs that contribute to this process. But I don't think it is our job to go beyond this in relation to socioeconomic aspects.

On the other hand, other elements of the Public Health Service, particularly the community health part of the Bureau of State Services, have the authority to conduct certain experimental ventures in attempting to modify some of the environmental factors. Essentially, though, the underlying socioeconomic problems relevant to the socially deprived child and the aged are being approached by the welfare agencies rather than the health agencies.

Mr. BROWN. My line of questioning is aimed at trying to identify the importance of social science and the degree of support that is being obtained for it through both NIH and NSF. When we discuss the behavioral sciences, the environmental sciences, we are talking about the social sciences; we are talking about basic economics, sociology, psychology, which are not generally considered to be biological or physical. I would like to have you comment on the amount of support which is going into these areas from the NIH.

Dr. SHANNON. Could I make one statement before commenting on the amount? I will give you a rough figure, and we will correct it in the record.

First, we have no category of support for the social sciences as such. On the other hand, within the social sciences are the elements that I spoke about earlier; that is, psychology, cultural anthropology, and so forth. Our figures would indicate that in the aggregate we are spending about 10 percent of our total resources in the social sciences. But this is spent only in those areas where our program staff see peculiar relevance to problems of health. But if I may, I will insert in the record the dollar value and the institute involved in these expenditures.

NHI—National Heart Institute.
NIMH—National Institute of Mental Health.
NINDB—National Institute of Neurological Diseases and Blindness.
DRFR—Division of Research Facilities and Resources.
OIR—Office of International Research.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. No questions.

Mr. DADDARIO. Mr. Vivian?

Mr. VIVIAN. On page 6 of your testimony, you say: "NIH is not primarily a science agency."

On page 2 you indicate that it has as its primary mission "the support of medical research."

Dr. SHANNON. There may appear to be some inconsistencies because I did some editing last night to my remarks as you have them there. In any case, the sharpening up of what our mission is stems really from the Wooldridge Committee, that analyzed our activities from the standpoint of the relative degree of the excellence of the research work that we supported. They looked at the distributed parts, rather than at the whole of NIH, and came to the conclusion that we

were an agency not too different from the National Science Foundation except that we concentrated our activities in the biomedical field while the National Science Foundation concentrated on the physical sciences and mathematics. We take a different view, based on the total thrust of NIH concern; we are a health agency. We exist purely for purposes of finding solutions for disease and an understanding of health. However, these purposes require establishing a very broad base of fundamental research because of our ignorance of certain areas in the biological sciences, and our inability to find answers of an applied nature at this point in time. So our mission is a social mission; namely, the conquest of disease and the provision of buoyant health; but the devices we use to find answers to these problems are highly scientific. The Department of Defense also has a social mission; to conserve the physical and moral integrity of our Nation; but it also uses science in no small measure as a means toward that end. Our end is the conquest of the disease and the maintenance of health, and we use science to achieve that end.

Mr. VIVIAN. I had the impression that NIH's mission was not the conquest of disease, but providing knowledge as to the conquest of disease. You indicated before to Mr. Brown that you were not trying to cure mental disease, but how it could be cured, and what the problem is.

Dr. SHANNON. That is not entirely correct, in the sense that we are a part of a larger agency, the Public Health Service.

Mr. VIVIAN. That I agree with, but NIH is specifically related to determining the cause of disease.

Dr. SHANNON. If you extend that to the means whereby cure can be accomplished.

Mr. VIVIAN. I didn't wish to exclude that.

Dr. SHANNON. We are primarily the research arm of the larger structure called the Public Health Service, and it is from this perspective that we state our mission as I have stated it to you.

Mr. VIVIAN. If the Public Health Service's goal is the improvement of the health of the Nation, then in a sense social sciences would presumably be part of the Public Health Service, whether or not in NIH?

Dr. SHANNON. This is why I mentioned the Bureau of State Services. The segment of that Bureau that deals with community health does have certain experimental procedures that relate to the handling of our elderly citizens and modifying the environments relevant to health problems.

Mr. VIVIAN. I am not sure whether on page 6 your present remarks exclude the phrase, "Though NIH is not a science agency." However, I have difficulty in understanding why it is not primarily a science agency.

Dr. SHANNON. I suppose what we get involved in is how we use words, what they mean to you, sir, and what they mean to me.

Mr. VIVIAN. Let me go to page 9:

> The Science Foundation has added a separate sheet covering medical and health-related activities.

I construe this as meaning that ordinarily they would not have covered medical and health-related activities because they are not pertinent to the Science Foundation's coverage area?

Mr. MURTAUGH. That is not quite correct. In their collection of data they would not have identified as a category those activities of a foundation directed toward the medical and health area which we would be interested in.

Mr. VIVIAN. Why not?

Mr. MURTAUGH. They would be included in the total. For instance, they would identify the research expenditures of a foundation directed toward broad areas of science. We have worked with the Science Foundation in attempting to obtain detailed breakdowns of this reporting to identify specific areas of interest to us; just further detail is all.

Mr. VIVIAN. My impression is that the Wooldridge report has a good deal of validity in reference to the NSF–NIH relationship. I am not at all convinced that the present relationship is a very wise relationship or the best one. I will come back to that one in a moment. Is there any mission in the field of health which is allowed to NSF?

Dr. SHANNON. In health per se I would say, no, sir.

Mr. VIVIAN. There is no mission in defense normally——

Dr. SHANNON. In defense there is, sir. In defense there is a very specific health mission.

Mr. VIVIAN. I am sorry, I am saying I believe there is no mission in the defense area which is allowed to NSF.

Dr. SHANNON. I am sorry. This I don't know.

Mr. VIVIAN. There is presumably no mission in transportation in the sense that NASA covers the upper space transportation and the Commerce Department covers the lower space transportation. I want an answer to the question what mission, if any, does NSF have?

Dr. SHANNON. It depends on how you define mission. I think I view the need for (or, if you will, its mission), in this way: Take a national situation wherein one must create a very broad program of research and development in order to accomplish the essential social missions—defense, health, or what have you. To accomplish these social missions, one requires an extraordinarily sound general purpose scientific establishment within the Nation, both for the education of our people and the training of scientists. I think NSF's mission then is to assure the soundness of this general purpose scientific establishment. One way it does this is to assure support for all the science areas basic in nature, from which we know will come in time the research insights and developmental opportunities that then become useful to the mission-oriented agencies.

Mr. VIVIAN. I asked this question not for the purpose of giving you a hard time but for a different reason, and that is NSF does seem to be—the phrase "balance wheel" has been used—but the phrase "filling in the cracks" seems to be somewhat more apt label. I have difficulty in seeing the relationship between NIH and NSF, and in solid state research between DOD, NASA, and NSF. Have there been any changes in NIH policy as the result of the existence of NSF? In other words, what changes have occurred in NIH policy as a result of the fact that NSF came into existence? I suppose this is complicated by the fact that your agency has changed so enormously it is hard to know which came first.

Dr. SHANNON. I think the existence of NIH (and of other mission-oriented agencies supporting science) has changed the NSF concept, rather than the other way around. NSF, as it was originally conceived, was to be the scientific establishment in the Government that would cover not only the physical sciences and mathematics but all science areas, including those relevant to health and disease. Indeed in the original report spelling out the NSF concept, there was a substantial segment assigned to the area of the medical sciences. But when NSF came into being in 1950, NIH already had established seven of its eight present categorical institutes. We already had a going program in a wide variety of research areas, both applied and fundamental; and these facts were taken into account in developing NSF programs. However, it is also true to say that the establishment of NSF indeed conditioned the further development of NIH.

Let me be quite specific about certain areas. We have an overlap, for example, in chemistry. You will find that we support about half of the chemistry and NSF supports about the other half. Moreover, this is an area where it is sometimes hard to say whether NIH or NSF should support a particular project. The chemistry we support is that which can be rationalized as relating in one way or another to the biological structures we deal with or to the ability of chemicals to influence those biological structures (the development of therapeutic agents and the like). NSF, however, in a comparable area, would be less concerned with the interaction of chemicals with biological systems than it would be, for example, in synthetic organic chemistry for its own sake. So that while chemistry is supported by both agencies, there is a sharp cleavage in general between that which we support and that which the National Science Foundation supports. It is true, though, that there is some overlap. But if there were no overlap, there would likely be a broad deficiency. I think our attitude would be that so long as the same criteria of excellence are applied by both agencies, then in this overlapped area where research grant applications can go to either agency, it probably doesn't make too much difference.

Mr. VIVIAN. My comment might be that one of our difficulties in trying to set budgets for various agencies and departments is that it is very difficult to know whether there is a proper correlation between the agencies or unnecessary duplication.

Let me ask three questions very quickly. You are probably aware of the proposed environmental sciences group or department which is an attempt to combine several other units, such as the Coast and Geodetic Survey, the Boulder Laboratories, and so on. Do you have any views which you would like to express briefly on whether or not that is desirable in the present structure or would you prefer to avoid that question?

Dr. SHANNON. From what I know of it I would say it is highly desirable. I would point out that in this area there will be a comparable type of overlap with NSF as with ours.

Mr. VIVIAN. That is correct.

Dr. SHANNON. There could also be some overlap between this new structure and the environmental sciences programs of the Public

Health Service which seek solutions to problems of hostile environment such as water pollution, air pollution, and the like.

Mr. VIVIAN. Who supports psychologists? I suppose the psychiatrists are supported by NIH.

Dr. SHANNON. I think we support the largest segment.

Mr. VIVIAN. You do clearly support psychologists as psychologists?

Dr. SHANNON. Yes, sir.

Mr. VIVIAN. Does NSF?

Dr. SHANNON. I am sure they support psychology.

Mr. VIVIAN. I would appreciate some knowledge of what projects are conducted in this area.

The neurology of the brain is related to the biochemistry of the brain. Is there a major program which I will call the phenomenon of the human brain in which all of the informational sciences are applied to the subject, is this an active subject in your Institute at the present time?

Dr. SHANNON. Yes, sir; it has two primary poles around which the programs develop. One is the Brain Institute developed under the auspices of UCLA. This is an interesting institute because it is almost exclusively supported by Government; I think to the point of about 95 percent. We can get precise figures if they become important.

Mr. VIVIAN. I wonder if you could provide me with some material on this either in written form or by having some person come to my office at sometime in the near future?

Mr. DADDARIO. I think it would be helpful if you could provide that for the record. I am interested in further information on the Brain Research Institute. I visited it a few years ago as it was being formed, and it would be helpful for the record if we could see what kind of contribution it has made in view of the question and the remarks you have made.

(The information requested is as follows:)

The Brain Research Institute of the University of California at Los Angeles began to take shape in the early fifties under the leadership of Dr. H. W. Magoun. He encouraged members of many different departments interested in the nervous system to develop closer relationships, so that they might become more effective; also to broaden the scope of their investigative activities. This endeavor eventually resulted in institute status being assigned by the University of California late in 1959. A building to house the research projects was constructed and occupancy began in March 1961. The structure contains 76,000 square feet of space. The official opening of the Brain Research Institute was held on October 14 and 15 in 1961.

The Brain Research Institute operates under a director and an advisory committee appointed by the chancellor upon recommendations of the dean of the medical school. Members of the Brain Research Institute are elected by action of the advisory committee and director in recognition of their established capability in brain research as indicated by their research accomplishment. During the period July 1, 1963, through June 30, 1964, there were 68 members, 10 associate members, 12 visiting members, and 5 consulting members of the institute. These were from 14 departments, 12 of which were in the school of medicine, and 2 from the college of letters and sciences. (All members of the institute must be members of some department of the university.) In this capacity all the academic members (appointments at the level of assistant professor or higher) are able to assume some teaching responsibilities in the undergraduate medical students and graduate divisions. Some have less teaching responsibility than others depending upon their position in the school. However, all members of the institute devote their main research effort toward the advance of knowledge in function and structure of the brain.

The efforts of the Brain Research Institute, which cross many disciplinary lines, may be grouped under three headings: (1) "Project Research," (2) "Program Research," and (3) "Research Training."

"Project Research" is research carried out by an individual investigator; there are some 114 of these projects covering almost all biomedical disciplines.

"Program Research" is used to describe interdisciplinary research activities involving several investigators from more than 1 to as many as 14 separate departments. Common among these programs are the Brain Information Service, the Cardiovascular Research Laboratories, the Clinical Neurophysiological Unit, the Data Processing Laboratory, Marine Biology Laboratory, the Space Biology Laboratory, and the Visiting Scientist Program.

The "Research Training" programs train investigators for independent careers in research. These investigators are at all levels of professional development and are subject to the interdisciplinary activities which characterize the entire institute. The curriculum sponsored by the institute emphasizes both formal disciplinary science education and less formal seminars and lectures. There is a special training committee which is responsible for coordinating education in the program with departmental requirements for the trainees. University departments represented on this committee generally include all of the biological sciences (though botany may be an exception).

The source of funding for the Brain Research Institute is as follows: 3 percent from the State, 4 percent from private foundations, 57 percent from NIH, and 36 percent from other Federal agencies. The budgetary allocation is 84 percent for research, 9 percent for training, and 7 percent for fellowships and facilities. The breakdown of this data is given on three tables copied from the 1964–65 annual report of the Brain Research Institute.

TABLE I.—*Brain Research Institute funding*

	Number grants	Amount
Grants to BRI members		$4,821,716

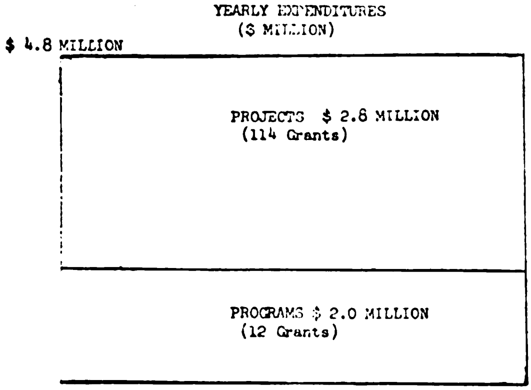

Fig. 3

Mr. DADDARIO. We do have a quorum call. I want to thank you, Dr. Shannon, and Mr. Murtaugh, too, for your wonderful contribution to this committee. I regret we do not have more time for questions, but I would like to send a series of questions to you for the record.[1]

This committee will adjourn until tomorrow morning at 10 o'clock at the same place.

(Whereupon, at 12:50 p.m., the committee was adjourned, to reconvene at 10 a.m., Thursday, July 15, 1965.)

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

THURSDAY, JULY 15, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order.

Our first witness is Dr. Augustus B. Kinzel, who is the president of the National Academy of Engineering, and who has been of help to this committee in the past. We are pleased to have you here this morning, Dr. Kinzel. We recognize that you have some other responsibilities this morning, so we will proceed immediately.

Dr. Kinzel. Thank you, sir.

STATEMENT OF DR. AUGUSTUS B. KINZEL, PRESIDENT, NATIONAL ACADEMY OF ENGINEERING

I have prepared a very short statement and I am, of course, prepared for questions. It is both a pleasure and a duty to respond to your invitation.

As to my qualifications:

Presently, I am vice president, research, Union Carbide Corp. At the end of this month, on reaching mandatory retirement age, I take on duties as president and chief executive officer of the Salk Institute for Biological Studies. I am president of the National Academy of Engineering and a member of the National Academy of Sciences. For the past 43 years I have worked in science, engineering, and research administration. During that time I have been consultant to and chairman or member of advisory committees to innumerable Government agencies. I have also held the presidency or chairmanship in many major engineering societies and organizations.

In commenting on the activity of the National Science Foundation, I would emphasize that science, per se, yields only knowledge. It does not, of itself, stimulate the economy nor does it, of itself, provide a high standard of living. It is the engineering step based on the new knowledge which results in directly stimulating the economy and providing the high standard of living.

Traditionally, this engineering step has been carried out by private enterprise, and the result is a tribute to its effectiveness. However, even though engineering is primarily the job of private industry, Government financial aid is essential in certain areas.

For example, when the effort is primarily for a governmental function, such as defense, Government must provide dollars for the engineering fundamentals as well as the specific engineering. In addition, there are many other areas where engineering fundamentals can be properly supplied through financial support from Government; witness, the recent meeting of the National Academy of Engineering dealt with earthquake resistant structures. Here there is no private organization large enough, or with sufficient incentive, to pay for the studies. Again, studies of fundamental properties of materials can be provided by private enterprise, but there are many materials having such special uses that private enterprise cannot justify the cost of studies. Further, there are basic engineering systems, such as the functioning of columns, rotating machinery, energy transmission by fluids, and the like, where studies of the laws of behavior would be of great benefit to all. Here, the National Science Foundation can and should play a much larger role.

The National Science Foundation has professed its intent to increase emphasis on engineering, and with respect to these figures I have a reference to the report which has been issued—yet, the proportion of its dollars directed to engineering as distinct from science is essentially unchanged and remains at a very low level. In 1964, that proportion was 11.2 percent of the total and in 1966 it is 11.8 percent. Moreover, the proportion of dollars for engineering research facilities in 1966 to dollars for total special facilities is only 3.5 percent.

Further, in 1962, total Government dollar support of the engineering sciences was 7.4 percent of the total Federal dollars for basic research and in 1965 it was 6.6 percent. When we consider that one true objective of Government support programs is to increase the economy and the standard of living rather than knowledge, per se, the proportion the National Science Foundation devotes to the support of deriving useful results from knowledge would seem to be decidedly less than best judgment would dictate. Perhaps we should not expect otherwise when we recognize that historically the Foundation is almost entirely staffed by physicists and other scientists with very few engineers.

Correlatively, a similar, if not worse situation exists with respect to engineering fellowships, particularly at the graduate level. There is a woeful lack of National Science Foundation fellowships in this area. More particularly, very few fellowships are applied to students interested in engineering design. The facts, figures, and arguments in this area should come from those directly engaged in engineering education, but I bring it to your attention as an item of major concern to the engineering profession.

To conclude, in spite of the decision to increase support of engineering by the National Science Foundation, inertia and pressure within that organization have resulted in failure to effect the desired change. This should be rectified, in my opinion, by budgetary legislation. In addition, executive action should increase counter pressures within the organizational structure and on the personnel of the National Science Foundation.

Mr. DADDARIO. Dr. Kinzel, could you amplify your last paragraph? Specifically, to what executive action are you referring? What is the

inertia pressures within NSF which have resulted in a failure to effect these changes?

Dr. KINZEL. I will attempt to so do. As you realize, we are dealing with something a bit intangible here, but I will speak to it nevertheless. The National Science Foundation is staffed almost entirely by physicists, chemists, and other scientists. It was so set up originally, historically. These men, with the best will in the world, when they apply their judgments, because of their background naturally give greater weight to things strictly scientific as distinct from the applications and the engineering. I happen to know that some of the members of the Board of the National Science Foundation have been concerned about this, but, in spite of the fact that everybody agrees that it should be done, it doesn't happen. With limited funds and many demands on these funds, the people who have their disposition at hand naturally are inclined toward that which they have been doing and which has been more or less acceptable on the one hand, and that which they are inclined to by virtue of their training. Now, I think this could be helped if topside in the National Science Foundation really made a major point of having this situation corrected and issuing either formal or informal directives to this effect.

Mr. DADDARIO. Then it is a question of emphasis on personnel who would have a tendency to support engineering rather than the sciences?

Dr. KINZEL. As far as this inertia and pressure is concerned; yes.

Mr. DADDARIO. You are the president of the National Academy of Engineering. Has this been recently organized?

Dr. KINZEL. Very recently.

Mr. DADDARIO. You are also a member of the National Academy of Sciences. Now that the National Academy of Engineering has been formed, do you think its relationship to the National Academy of Sciences and in turn to the National Science Foundation is a step in the right direction? What effect do you think this might have in bringing about the results you would like to see, insofar as emphasis is concerned?

Dr. KINZEL. It is a step in this direction, you are quite right. On the other hand, it is the kind of a step that is going to take a long time to be really effective. I think in this situation we need more timely action than you will get this way.

Mr. DADDARIO. You are looking forward to this end, but because it might prove to be rather slow, your suggestion is that a directive be issued either from the Director of the National Science Foundation, or from the executive branch or from the Congress. Is that correct?

Dr. KINZEL. That is right, to force it. That is precisely my suggestion.

Mr. DADDARIO. Mr. Roush?

Mr. ROUSH. I have no questions, Mr. Chairman.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. Would you agree that the United States has lost the world lead in applied science as opposed to basic science?

Dr. KINZEL. No.

Mr. CONABLE. Do you think that we are still preeminent in this field?

Dr. KINZEL. I do.

Mr. CONABLE. The statement has been made by some scientists appearing before us that this is a result of our emphasis on basic research. Do you think this is present also in the lack of interest by the National Science Foundation in engineering?

Dr. KINZEL. I think that has been one of the factors. I think it is less so today.

Mr. CONABLE. You feel that we still are preeminent.

Dr. KINZEL. In the engineering area; yes, I do.

Mr. CONABLE. Are we turning out engineers as fast as Russia?

Dr. KINZEL. This is a difficult question to answer because if I answer it categorically from what I know the answer would be "No," but when you say engineers you have to specify, and I would say that we are turning out a type of engineer today, certainly in the schools, let's say the top schools, a type of engineer today that is certainly the equivalent of anything that is being turned out anywhere else. As to the numbers, we don't know what we are going to need. The manpower report put out by the Killian Committee, of which I was a member, dealt with this at great length. We pointed out that some years ago, about 1952, it was predicted that there would be a terrific dearth of engineers, we just wouldn't begin to have enough, yet about 1958 they couldn't find employment and today there is no trouble hiring engineers. But the quality is the problem. There will always be a shortage of the top percent, but it helps if we can bring the whole level up, and this is what is happening actually in the schools today. In order to bring that level up, though, you must encourage the continuation of studies. That is what I was referring to in the National Science Foundation's fellowship program, which is directed almost entirely to the sciences, where engineers really have a rough time trying to find a place.

Mr. CONABLE. Thank you.

That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Brown?

Mr. BROWN. Dr. Kinzel, we have been differentiating in these hearings between basic research, and applied science and engineering, although the distinction has not always been too clear. Obviously, the engineers are getting the benefit of the vast amount of money spent in applied science and engineering. The work of DOD and NASA in building hardware is where the engineers are getting the preponderance of opportunities as distinguished from basic research. Obviously, in these mission-oriented agencies we are not covering the whole gamut of engineering. I gather from your remarks that there is likely to be the same gap, in what might be called basic engineering, as there would be in science. Is this essentially correct?

Dr. KINZEL. Yes; this is absolutely correct. The mission-oriented agencies by their very nature must give support in specific areas. Now, it is certainly true as a result of their activities a great deal of engineering work is going on. But fundamental engineering is supported only in small measure here.

There is a broad area in engineering underlying all engineering philosophy and approach, and here you must have people who are free to work without having a specific mission in mind, although you must have a specific set of problems in mind. I mention here the subject of energy transmission, frequency of vibration of rotating ma-

chinery. There is a great deal that we would like to know about rotating machinery, synchronous vibrations and the like, that is a proper function for study as an item of basic engineering. And this sort of thing falls between the slots.

Mr. BROWN. Is that field called systems engineering? Is it a respectable branch of engineering or does this term cover various areas of this science?

Dr. KINZEL. To answer you first categorically, yes, it is a most respectable branch of engineering, and what is happening in the engineering world today is that with the new knowledge we have to build systems, we have to build them fast, we have to build them without the experience of the past because they are so new and the phenomena are so new and there has been no time to develop experience. The experience is still there and is still necessary with respect to all of the component parts or practically all of them, but the way in which these are put together, the way the system is built is a very high form of engineering.

Mr. BROWN. It seems to me that one essential element in the systems engineering is the identifying of problems on a large scale, which so far we have not done too well. In other words, it is not correct to simply describe it, but to recognize that there is an area of problems which by the application of appropriate technology can be solved through what we call systems engineering. It seems to me that this is an area in which more research or study is necessary at the present time.

Dr. KINZEL. You are quite right in the opportunity, but it is easier to state the fact that there is the opportunity than there is to put your teeth in it. You get hold of a problem like transportation needs in the United States, for example, you get hold of a problem like that——

Mr. BROWN. That is exactly what I have in mind.

Dr. KINZEL. As far as vehicles are concerned, highways, roadbeds, airports, these are the components of the problem, but the system is putting the whole thing together. Now, we haven't had the mechanism to set this up in the past. I think probably we are getting to it now with the changes here very recently, but along with that there will be things that require special studies. It is like a jigsaw puzzle where you have a lot of pieces but there will be a few pieces that you don't have, they have to be made, and this is where your engineering research comes in.

Mr. BROWN. And this is something you feel the Foundation should support?

Dr. KINZEL. I think the Foundation should be playing a role in this primarily because they are not mission oriented. I give a parallel in the large corporations, in some of them at least, where there is a decentralized research and development system. You have individual divisions with research laboratories working on special things. They are mission oriented, product oriented and process oriented, but in addition to that they have a small central laboratory—by small, I don't mean really small, but small in proportion to the grand total, 10 percent or something of that magnitude—where they are working on problems basic to all of the specifics, to all of the missions as it were, and this is where I visualize the National Science Foundation

in the picture, as playing that role, that is, that role in the sense of financing and guiding for the Government.

Mr. BROWN. Somewhat related to this is the application of engineering—basic engineering and basic systems engineering—to large parts of the world which are economically behind the United States. We really have a massive problem here in quickly closing the technological gap. Do you believe that there is an area of basic engineering research involved in solving this type of problem?

Dr. KINZEL. Yes, but probably a little different from what you have in mind from the way you put the statement, sir. I frequently think of engineering as the bridge between science and people. Now, you have a strong science with a bridge at one end and you have to have people that accept it at the other end. I don't think it will help very much to put a big engineering system of transportation highways and whatnot into the Congo at this time, just to pick one out of the air.

So the engineering in these developing countries has to be geared to the level of the standard of living, maybe one peg up, but not a thousandfold up. So you have a very special kind of a problem. I think that this problem requires study, but not the kind of study that I think of as fundamental engineering. It is really a study of the relationship of the economic engineering on the one hand to the level of acceptability and receptiveness of the population on the other.

Mr. BROWN. Thank you.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. On page 2 of your statement, Dr. Kinzel, there is a remark on engineering research facilities. I would like to know what you mean by engineering research facilities as opposed to research facilities in general.

Dr. KINZEL. This was taken from the Report of the Science Policy Research Division Legislative Reference Service of the Library of Congress, entitled "The National Science Foundation Agency Review of Its First Fifteen Years."

As I understand it, the way those figures were put together, and they were put together with the help of the National Science Foundation, those facilities which were specifically for scientific investigation, for example, a new accelerator or something of that kind, a Van du Graaf machine and so on, are listed as special facilities for scientific research, whereas if you had a new kind of a testing machine, coming back to the rotating machine, a stroboscope or other advanced instruments to learn more about the nature of vibration, this would be an engineering facility. Have I differentiated those?

Mr. VIVIAN. I often find them extremely difficult to differentiate. I think in education there is a great distinction, but in research facilities it is minor. Let me come back to the engineering sciences. You state that the support of engineering sciences was 7 percent in 1962. What do you mean by engineering sciences?

Dr. KINZEL. Again I take it as a direct line from this same document, and here as I understand it, the engineering sciences has to do with fundamentals of materials and fundamental behavior of structures.

Mr. VIVIAN. For example, Dr. Harvey Brooks, who I expect you probably know, was here yesterday. He is a very able and interesting person.

Dr. KINZEL. Most.

Mr. VIVIAN. He believes that engineering contains indications of theory and fluid dynamics. I happen to be a graduate engineer, and I can easily construe those as science, and it appears to me as an unanswerable argument. I believe that the distinction between engineering science and scientific engineering is a matter which is largely subjective and not objective. Therefore, I shall have to go back to the authors of those documents to which you refer to determine what they have in mind.

Dr. KINZEL. May I comment on that. Your point is very well taken, but it is like everything else where you have a gray area. We can all cite many, many things where there is no question in anybody's mind this is science and many, many others where there is no question in anybody's mind this is engineering. In between there is a gray area, and any time you have a gray area you are faced in certain specific cases with the quandry or the problem which you have just raised. But this is a small part of the grand total. I have long ago stopped letting definitions keep me from doing the job because of the 10 percent area or the 15 percent gray area that isn't covered. It is subjective, everything you have said is true, only it applies to only about 10 to 15 percent of the total areas.

Mr. VIVIAN. As an engineer, I personally feel it would be better for the National Science Foundation to have more engineers as you have suggested. Likewise, the National Academy of Sciences should have had more engineers rather than necessarily splitting into fractions.

Dr. KINZEL. May I comment on that? As far as the National Academy of Science having more engineers, because of the historic background and the way membership was put up, it couldn't be done. Many of us tried very hard to do it. This is why we set up the National Academy of Engineering, and we have set it up under the same Act of Congress under which the National Academy of Science was set up and we have set it up in such a way there will be a major degree of coordination.

Mr. VIVIAN. I hope we do not have another fraction such as a National Academy of Engineering Sciences, or a fourth academy called the National Academy of Applied Engineering.

Dr. KINZEL. Those steps are possible, but I concur in your hopes.

Mr. VIVIAN. In Dr. Brooks' remarks he said:

> In general I feel that the National Science Foundation should be cautious about entering applied science areas, and I think it should consider doing so mainly in those areas where the support of applied activities would clearly make an important contribution toward a more balanced advanced training of technologies.

I think this could also be labeled retraining as well as training. I gather that goes along with your own comments on the matter of fellowships.

Dr. KINZEL. There is nothing contradictory with what I have said at all.

Mr. VIVIAN. You would, therefore, like to have an increasing portion of the funds clearly identified for the application of science rather than the expansion of basic scientific knowledge. This comes

directly into line with the activities of Mr. Holloman's group in the Department of Commerce, which I will come back to in a few moments. The question in a sense then may not be that NSF's funds should be increased or that the funds in some other agency of the Government should be increased, but rather that the National Academy of Engineering should, perhaps, be more closely related to the Department of Commerce than to the National Science Foundation in its historic evolution.

Dr. KINZEL. May I just interject on that point?

Mr. VIVIAN. Yes.

Dr. KINZEL. I am fully appreciative of the points you have just made. The thing that we have to watch out for is that when you put certain problems into the Department of Commerce, incidentally, I am all for it, that they, too, do not become in a sense mission oriented, and the great advantage of the National Science Foundation is that there is very little chance that it will be ordered to be or designated to be mission oriented. I think this is the big difference. I am all for flexibility, too. I think that putting all your eggs in one basket, one Government agency basket, is not healthy.

Mr. VIVIAN. In view of the indicated indecision as to the gray areas I am sure there will be plenty of support which goes in all directions, somewhat like a fountain splashing off a splash plate, in fact.

I would also like your comments on this statement by Dr. Brooks:

> The National Science Foundation should in general stay out of the area of applied research except in cases where extension of its authorization to applied research would clearly contribute directly to its responsibility for the advanced education of technologists.

He was repeating the idea that NSF should stay out of engineering except in terms of training engineers.

Dr. KINZEL. I go further than that. I agree with him that it should be in the area of training. I believe it should also be in the area of fundamental engineering.

Mr. VIVIAN. What is "fundamental engineering"?

Dr. KINZEL. Those things which do not apply to a specific goal. For example, we have had this rotating machinery example, so I will stick with it. You work on rotating machinery, you don't work on a new turbine or a new pump or something of this kind, you work on the general problem having to do with all rotating machinery.

Mr. VIVIAN. I find that very hard to differentiate from science. It seems to me that engineering arises in the question of scientific knowledge in terms of which approach is better from a dollars and cents point of view or which approach is better from a health point of view or some other matter. Perhaps we should not engage in semantics. You may comment so we will come out even.

Dr. KINZEL. I have no desire to come out even. I am just trying to be helpful.

Mr. VIVIAN. Dr. Brooks also has commented:

> I feel that more use should be made of industrial scientists on the panels which evaluate engineers.

Do you feel that industrial scientists and engineers are well represented on the panels of NSF?

Dr. KINZEL. They are pretty well represented, but I think they could have better representation. This is one of the things where the National Academy of Engineering is going to work with the National Science Foundation to see if we can't help out.

Mr. VIVIAN. Another statement drawn from Dr. Brooks' remarks is:

Part of the problem of applied science is that 65 percent of all university engineering research is financed by defense and space agencies, and this has tended to orient both students and faculty away from interest in the problems peculiar to the design of products, processes, and systems where economic and political constraints are of primary importance.

I am quite familiar with this question. In a sense it is not too efficient to take individuals who have been trained in particular military applications of science where cost is somewhat secondary and to retrain them to, say, start making pots and pans, where cost is extremely important and functional performance must be very carefully geared to cost. Do you have any comments on this subject?

In other words, does the Government wisely assist in the training of technologists and engineers for commercial futures as opposed to what I will call Government futures?

Dr. KINZEL. I find it hard to differentiate. I think we are in another gray area. Let me put it this way, that the funds given by the Department of Defense and other mission-oriented agencies are generally very specifically directed, and they have to do with, in the case of training, with training people for very specific functions, not for training them and rehabilitating them in the sense of bringing them up to date and taking the college graduate of 10 years ago and seeing that he is equal to the college graduate of today, which is a different kind of an approach, and it is this second one that I think is the function of the National Science Foundation rather than one of the mission-oriented agencies.

Mr. VIVIAN. Let me switch then to another subject. One of the problems that arises in training engineers is giving experience at a design level as opposed to a study level. Again I could quote from some remarks by Dr. Brooks which I think were very intelligent on the subject, but I will refrain merely to save time.

Is there any procedure by which engineers can be trained in the realities of designing for a customer's requirements more effectively as opposed to simply learning more of the basic science of the subject?

Dr. KINZEL. I have touched on this same thing here. In the graduate work, in particular, there is a strong tendency, simply because again of the way the universities are oriented as well as the National Science Foundation, there is a strong tendency to take men that are working toward a doctor's in engineering and giving them a problem in this gray area that we are talking about that is so far over on the science side that it is almost the same kind of a thesis that the man would be working on if he were working toward a doctor of science, and actual design problems as a doctor of engineering these are very hard to find any place. Now, how to rectify this is not simple, but if a certain number of your fellowships were specifically designated for this purpose, then I think the university people would give the whole matter some more thought and you would find the thing going in that direction.

Mr. VIVIAN. Dr. Brooks pointed out that doctors have an internship period during which they proceed to administer curative measures to patients. In a sense, they practice their trade very intimately. Engineers generally do not have such an immediate opportunity in the training process specifically for the design of hardware, except as a consultant. Many persons become consultants at an early age and do design work even though their education is still progressing. Can you suggest a better way to have such a person gain design experience? I am thinking in terms of an industrial intern as opposed to a medical intern.

Dr. KINZEL. Of course, the so-called cooperative programs are not new, whereby a student spends a certain amount of time in industry. This is one effective way of doing it.

Mr. VIVIAN. Are these programs being supported by the Government to any significant degree?

Dr. KINZEL. To the best of my knowledge they are not.

Mr. VIVIAN. Do you think it would be desirable or undesirable?

Dr. KINZEL. I think it would be desirable.

Mr. VIVIAN. Despite the competitive involvement?

Dr. KINZEL. As long as they are students, I don't see any competitive involvement there.

Mr. VIVIAN. The National Academy of Sciences has a contract with the Atomic Energy Commission to evaluate the proposals for construction and the sites for a proposed new high-energy accelerator. From my point of view the design and installation of that accelerator is basically an engineering job rather than a scientific job. If the National Academy of Engineering had existed for 10 years and was a stable organization with an established membership, procedures and clientele, would you have construed this as a task that would have gone to the National Academy of Engineering rather than the National Academy of Sciences?

Dr. KINZEL. Definitely. The way we are trying to get this thing set up, and I think we have got it, between the National Academy of Sciences and the National Academy of Engineering, is when a problem comes in of this kind, no matter which academy the problem is addressed to, it will wind up in the one best qualified to render the service. I think we have got the organization and the mechanics set up now so this will happen. To answer the first question, yes, definitely what you are talking about is primarily an engineering job.

Mr. VIVIAN. One can anticipate that 10 years from now we will build a larger accelerator and by that time the National Academy of Engineering will have been an established organization. I would gather that at that time we will not have to worry about an argument between the two academies as to which should evaluate the site?

Dr. KINZEL. The only comment I can make on that is I hope to goodness we can do it in 2 years rather than 10. I think we have got a good chance of doing it.

Mr. VIVIAN. Thank you.

Mr. MOSHER. Mr. Chairman?

Mr. DADDARIO. Yes, Mr. Mosher.

Mr. MOSHER. Dr. Kinzel, it is my impression that the National Academy of Sciences frequently acts in an advisory capacity to the National Science Foundation. You are president of the National

Academy of Engineering. Does your society frequently act in that same role, or do you anticipate that it will?

Dr. KINZEL. It is so new that we haven't yet, but we certainly expect to.

Mr. MOSHER. You anticipate a growing relationship of that sort with the National Science Foundation?

Dr. KINZEL. Definitely.

Mr. MOSHER. Do you see any advantages or disadvantages in a contractual relationship whereby the National Academy of Engineering might be an operating contractor employed by the National Science Foundation?

Dr. KINZEL. In the same sense that the National Academy of Science is; yes. But in the direct sense of being a contractor to carry out a project, there it would go into the National Research Council, which is run by both academies.

Mr. MOSHER. I was thinking of a contract whereby your Academy might undertake some applied research for the National Science Foundation.

Dr. KINZEL. To take the responsibility for the applied research; yes. I am distinguishing between taking on the responsibility and actually putting up a laboratory and doing it. This we don't want to do obviously.

Mr. DADDARIO. Dr. Kinzel, in reference to the desired changes you were talking about, I asked you some questions about the types of people and organizations within the Government which might be helpful to bring about this change. I did not refer at the time, however, to the National Science Board. How do you feel it could help in bringing about these desired changes?

Dr. KINZEL. There again a large part of its membership has been drawn from the scientific world, and I think a larger representation from the engineering world would be helpful.

Mr. DADDARIO. In a sense, the same criticism you had applies there as well?

Dr. KINZEL. That is right, but to a lesser degree.

Mr. DADDARIO. Dr. Kinzel, thank you very much. You have been very helpful to this committee.

Dr. KINZEL. You are very welcome, sir.

Mr. DADDARIO. Our next witness is Dr. J. Herbert Hollomon, Assistant Secretary of Commerce for Science and Technology. Dr. Hollomon has been before this committee on several occasions. We are always glad to have you here.

STATEMENT OF DR. J. HERBERT HOLLOMON, ASSISTANT SECRETARY OF COMMERCE FOR SCIENCE AND TECHNOLOGY; ACCOMPANIED BY GORDON CHRISTENSON, ASSISTANT GENERAL COUNSEL

Dr. HOLLOMON. Mr. Chairman, I have with me Mr. Gordon Christenson, Assistant General Counsel for the Department of Commerce, who has been particularly engaged in matters having to do with science and technology, industry, economy, from a legal point of view. He is sitting beside me at the table.

Mr. DADDARIO. We are pleased to have you.

Dr. HOLLOMON. I appreciate the opportunity to appear before you to discuss the National Science Foundation, its relationship to the U.S. Department of Commerce, and the role that the National Science Foundation has played in our national life since its establishment 15 years ago.

The past one and one-half decades have firmly established this era as an age of science and technology. The fact that this time span also encompasses the entire lifetime of the National Science Foundation is, of course, no accident of history. NSF is neither the sole cause of, nor an incidental consequence of, our present strong posture in basic research and science education.

The Foundation is a logical and vital institution in our Nation's total scientific and technical resources. The record of solid achievement of the National Science Foundation has been thoroughly documented in the course of these hearings. I can only echo those general sentiments that have already been expressed.

I should like to speak today from four different vantage points in examining the role of the National Science Foundation:

First, I am responsible for the supervision of several Government Bureaus involved in scientific and technical programs.

Second, as Chairman of the Interdepartmental Committee for Atmospheric Sciences of the Federal Council for Science and Technology, I have been able to observe the National Science Foundation as it functions with respect to large national research programs.

Third, I should like to comment from the point of view of a Government official responsible, in part, for insuring the effective use of research and development in the national economy. Finally, I should like to speak as a member of the scientific and engineering community.

The Department of Commerce has enjoyed cooperative and fruitful relationships with the National Science Foundation for many years. Frequently, these activities have grown out of national research programs, under which the National Science Foundation has supported research in a wide range of institutions, including Government, universities, and nonprofit organizations.

For example, the National Bureau of Standards, the Weather Bureau, and the Coast and Geodetic Survey of my Department have participated in the International Geophysical Year, Antarctic research program, International Indian Ocean Expedition, United States-Japan cooperative science program, and the International Year of the Quiet Sun.

The National Science Foundation has also made funds available for the initiation of important new programs in the Department of Commerce, which might not otherwise have been started when the need first became apparent. As in any human endeavor, new concepts and new ideas need to have an early means of support until they are able to justify an independent status. The national standard reference data system and the clearinghouse for Federal scientific and technical information were both supported, in part, by the National Science Foundation in their early stages. These programs are now generally of broad interest and utility, and have some support on their own merits.

In addition to these formal arrangements, there is a wide range of casual, though significant, contact between the Department of Com-

merce and the analytical and funding groups in the National Science Foundation. Particularly useful are the analyses and data that describe the nature and extent of research and development in the United States. I know that these contacts and this information have benefited the Commerce Department, and thereby the Nation, and I am certain that they have strengthened the overall Federal science activities.

Although NSF does and should support broadly applicable basic research programs, there is a question in my mind as to the extent to which NSF should go beyond basic research toward the practical application of the knowledge gained.

NSF must provide support for the basic research that is later used for practical purposes. However, as progress leads to operational phases, and to work lying within the scope of existing agencies, the suitability of NSF to carry on large-scale, nationwide programs is open to question. For example, I question the role of NSF in the practical, information-gathering aspects and developmental aspects of weather modification.

I believe the assignment of responsibility to NSF in weather modification has led to a loss of initiative on the part of other agencies to develop programs leading to useful results. A special commission of the National Science Board and the Interdepartmental Committee for Atmospheric Sciences is now studying the question of the role of NSF and other agencies in this field.

The Interdepartmental Committee for Atmospheric Sciences is composed of representatives from Federal agencies with responsibilities and interests in atmospheric sciences. The agencies support research and development in the fields that are pertinent to the fulfillment of their mission responsibilities. The National Science Foundation supports research that is designed to remove the scientific limitation on our understanding of natural phenomena. In this role, it has done an excellent job in benefiting of all those that have a responsibility or requirement in the atmospheric sciences.

But there is another question that should be examined. Is it desirable for an institution devoted to the conduct of atmospheric research—in this case, the National Center for Atmospheric Research, called NCAR, at Boulder—to be wholly supported by the National Science Foundation?

Should there be an institution fully funded by NSF for the specific purpose of understanding the atmosphere? Is it wise to have a situation where proposals come to NSF from the scientific community and compete for funds with one institution which is a creature of NSF? Being fully funded, the National Center for Atmospheric Research tends to become a creation of NSF without either educational or mission responsibility. What should be the relation of the Weather Bureau to NCAR?

This question has nothing to do with the quality of the research institution performing the work. It is a question of the appropriate roles of the National Science Foundation and of the National Center for Atmospheric Research.

In meteorology, there is now, and will be in the next decade, a much larger issue. We have reached the point where we need to take a look at the way we approach research related to the atmosphere, lying at

the root of weather prediction and modification. The advancing state of knowledge, together with the increasing capacity of our scientific tools—computers and satellites, for example—may provide the possibility of long-range weather predictions, or at least predictions further ahead in time than is now possible.

In order to determine whether the large perturbations of the atmosphere—the storms of the atmosphere—persist long enough to permit long-range, accurate predictions by computer, we will need a large-scale program of worldwide weather observations over the whole globe by ships, planes, buoys, and satellites. Computer analysis of the results will determine whether, with a global network, substantially improved predictions are possible. These problems involve far-reachings scientific and technical questions. They also raise questions of a different sort, such as questions of organization, policy, and responsibility.

Should the National Science Foundation support programs like this, or should the programs be the responsibility of the agencies that will have to put the results to work? This particular program will require large sums of money and many people.

Many Federal agencies will be involved, and global scientific planning is required. This type of project proposal does not originate with an individual researcher at a university. Proposal for work of this type would hardly come from a single institution. The project will ultimately be done by many nations working together. The administrative and organizational problems will be staggering. The question is, who should have responsibility for scientific tasks of this nature? In other words, what institutions or mechanisms are necessary for projects such as this?

Finally, I should like to speak from the point of view of one who is concerned with the relationship between science and technology and the advancement of the national economy. You have heard some remarks on that subject from Mr. Kinzel.

As I mentioned before, the National Science Foundation is a keystone in our efforts to develop the Nation's scientific and technological resources. Its long-term objectives should therefore be focused on building the institutions of science, rather than on the solution of specific scientific questions.

There are really two sets of institutions involved: science, as an institution; national and international in scope, and those institutions concerned with education, training, research, and the use of science.

To build and develop science, we need to support the leading people and their programs for study, as judged by the people best able to do so—the peers of the scientists themselves. In those areas of science in which it has been active, the National Science Foundation has made this Nation's science lead the world.

In my view, however, the definition of "science" used by NSF tends to be too restrictive. Our concern, and the concern of the National Science oFundation, should be directed toward science broadly. There should be a greater concern with the science of people and their behavior, with the institutions that people create, and the interaction of people with the environment and with their society. The problems center around transportation, communications, shelter, urban society, education, industrial production, and the economy. I

believe that our misunderstanding of these matters, which derive out of our national need, is limited, by comparison with our understanding of the more conventional subjects of science.

With its broad mandate for the support of basic research and scientific and engineering education, the National Science Foundation is a logical agency to focus our national efforts in these important fields. Other agencies have begun to support mission-oriented work in these fields, but NSF efforts have been modest.

These problems are commonly thought to be the more proper domain of engineering or of social science. Although engineering is concerned with the ultimate solution to problems, there is a science that underlies the new technologies we will need for a great society. NAF's relatively small effort in these fields, incidentally, should not be too surprising. Much of the research supported by NSF originates in proposals generated by individual scientists, mainly in universities. The proposals are forwarded to Washington for evaluation by committees of the scientist's peers. The primary orientation of the scientist is to present fads in fields of study. The orientation of the committee of peers is to these same fields. The forces in this system act to continue research in the traditional framework of science.

New ways must be found to encourage and stimulate research into the basic scientific problems that underlie industrial, economic, and social problems. These studies should be carried out largely in universities, where there is presently comparatively little activity. This endeavor will require leadership and initiative by the National Science Foundation, rather than being simply responsive to proposals, since it will not come about through project proposals by scientists and engineers now engaged in these fields. There are far too few people working in these areas to generate enough project proposals for an expansion of this type of activity.

The second responsibility for institution building by NSF requires support for the institutions that teach science and engineering, that train scientists and engineers, and are concerned with the use of science. For the good of the Nation, we must provide mechanisms that broaden participation in the decisionmaking process which determines the support of science and engineering. To accomplish this end the development of a large number of institutions in all parts of the country is required. There must be a broader base of support for a greater variety of scientific subjects. The ties of scientists to their institutions and institutions to their scientific staff members must be strengthened. Many centers of excellence must be developed. The translation of science to meet the local needs of society must be encouraged.

Institutional support programs, as contrasted with project support programs, best assure that we will meet these objectives. The Congress and NSF have begun to recognize this with new institutional support programs; support for them should be expanded and strengthened.

In the 19th century, we supported science in the framework of an emerging nation to exploit its natural resources, to survey and explore the continent, and to unite a large nation with communications and transportation systems. As a result, certain specific types of science emerged.

Today, we are a complex, interdependent, urban, technology dependent, international, highly mobile society. Our economy is dependent upon science and technology. We have passed from an agricultural economy to a manufacturing economy, and we are now moving into a service-oriented economy. Consequently, our support for science should be viewed within that framework. Today, as in the past, we need to support the science relevant to our needs as well as science which expands the universe of our understanding. We must support scientists and the institutions that generate knowledge pertinent to our times. We must also produce the people and the mechanisms to put the science to work to meet present needs, for if the needs are not met, the Nation will not prosper, and the science will not be supported.

To summarize briefly, the National Science Foundation has done a remarkable job, particularly with respect to the Commerce Department, in connection with broad national research programs. In my view, NSF should not take on responsibility for applying knowledge, or for operating development programs, except in the fields of education and science information. Finally, ways must be devised which will permit NSF to support researchers and institutions concerned with the broad social, technical, and economic needs of modern America. If these things can be done, NSF will continue to play its great role in the Nation's life.

Mr. DADDARIO. Thank you, Dr. Hollomon.

Mr. Roush?

Mr. ROUSH. Dr. Hollomon, you have made a very fine presentation, and I think we all appreciate the constructive criticism you offered.

I have no questions at this time, Mr. Roush.

Mr. DADDARIO. Mr. Davis?

Mr. DAVIS. Dr. Hollomon, I believe you stated that it was normal and perhaps desirable that scientific effort is supported by the ones who would profit from the fruits of the effort.

Dr. HOLLOMON. I didn't quite say that, but I believe that is generally the case.

Mr. DAVIS. Applying that thought to the meteorological research, everybody would, of course, be interested and profit by the fruits of that research?

Dr. HOLLOMON. What I said was, I felt not who would profit by it, but who would have to put the results to work.

Mr. DAVIS. Yes; that was your phrase.

Dr. HOLLOMON. That is a little different than the fellow who profits by it. You and I profit by improvements in weather prediction, for example, but the results are put to work largely by two agencies of the Government—the Weather Bureau, on the one hand, and the Military Establishment, for their particular purposes, on the other hand. I was referring to a program which derives out of the fact that we think we can make a big advancement in weather prediction. The question I raise is, should that scientific program be the responsibility of NSF or an operating agency that finally puts the results to work? It is basic science, it is fundamental science, and it is science that has to do with understanding the whole of the atmosphere, but it derives out of practical need and its results must be judged by their utility.

The question is, how do we mount a big scientific project of this sort? Who should be responsible?

Mr. DAVIS. I cannot imagine any more universally interesting and profitable area of work than this subject. In a sense, the Weather Bureau is acting as the eyes and the communications network as to what the weather is.

Dr. HOLLOMON. To analyze how to make the prediction and to improve it.

Mr. DAVIS. I do not know any group that puts the weather to work more than, say, the Department of Agriculture or the farming industry.

Dr. HOLLOMON. Yes; on the other hand, agricultural predictions are made for the Agriculture Department by the Weather Bureau.

Mr. DAVIS. I am simply discussing the phrase "put to work." For example, the maritime industry, it puts it to work in one sense of the word.

Dr. HOLLOMON. Yes.

Mr. DAVIS. Would it be too confining, then, to put something as big as NCAR under the Weather Bureau?

Dr. HOLLOMON. I made no such suggestion.

Mr. DAVIS. I would like to know what you think.

Dr. HOLLOMON. My feeling with respect to NCAR, at least at the present time, is that it should have support from more than the National Science Foundation, and that it should be supported by many agencies of the Government, and that its support should not be uniquely the National Science Foundation's.

Mr. DAVIS. In view of the universal interest in weather, wouldn't it be necessary for it to be supported by almost every Government agency in order to come up to the ideal?

Dr. HOLLOMON. By all those who have a real interest in it. I think that would be very desirable.

Mr. DAVIS. I believe that is all, Mr. Chairman.

Mr. MOSHER. Dr. Hollomon, who should have the specific scientific responsibility for the weather program? Do you have an answer to that question?

Dr. HOLLOMON. No, sir; I do not. I don't have an answer to that question. Let me tell you what is going to be involved in such an experiment. In order to find out if we can take the next big step in the improvement in the prediction of weather, an experiment is required that will demand global observations on a 300-mile net, with measurements of six or seven levels of temperature, pressure, and wind velocity, using modern computers and so forth. This experiment will require the use of balloons, buoys, ships, and will be participated in by many countries and universities. The experiment will run 3 to 6 months. It will involve a major logistics problem.

How do we integrate all the required data? How do you get it done at the right time? How do you bring them together and analyze them? This will be a scientific experiment of broad scope, which requires, in order for it to be accomplished, essentially single management. It is not the kind of science you do in a laboratory. It is what Weinberg refers to as big science.

Mr. MOSHER. You have not said who should do this, but you have said, specifically, that in your opinion the National Science Foundation should not.

Dr. HOLLOMON. No; I have not said that. I simply raised the question, and I think it is an appropriate question for this committee to examine—should that be the kind of experiment that the National Science Foundation should fund or operate? Funding and operating do not have to be the responsibility of the same agency. The question here is, should the National Science Foundation fund it, and if they do, who is going to be the responsible agency for managing the project, or should the Weather Bureau fund for and operate the program since its purpose is to improve weather predictions.

Mr. MOSHER. Are you suggesting that this committee might make some recommendations on that subject?

Dr. HOLLOMON. I think this is a question which this committee ought to give some consideration. It should consider the philosophy which it believes NSF should follow.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Dr. Hollomon, in your paper you have stated very well some points that I have been badgering some previous witnesses about with regard to the role of the National Science Foundation regarding the solution of some of our social problems today. I am very pleased to see this. It raises a number of questions which your paper does not answer, unfortunately.

Dr. HOLLOMON. I wouldn't be presumptive.

Mr. BROWN. The bulk of the funding of the National Science Foundation goes to the support of what the witnesses for universities call basic science, but which turns out to be basic physical science—chemistry, physics, mathematics, engineering. The National Institutes of Health also fund the biological sciences and chemistry related to biology. These programs are justified on the grounds that this is pure science; this is basic research. Yet, it comes by no measure close to measuring the scope of the interests of the human mind, which is the basic concern of science. I pose this question: Suppose during World War II we hadn't developed the nuclear bomb which basically requires the extension of science in physics, chemistry, and math, but instead had developed a secret weapon which we will say involved psychology. Would not the major emphasis in the National Science Foundation today be upon the behavioral sciences and matters related to psychology, rather than physics and mathematics?

Dr. HOLLOMON. It is an "iffy" question, as you well know. I would say this, it is true that much of the motivation for the kind of science that we support in this country comes from the fact that we found that science is so dramatically useful for defense and space exploration. Much of the support comes from that general or emotional feeling.

Mr. BROWN. In other words, despite everything that we have heard and the fact that the National Science Foundation is not mission-oriented, nevertheless, the importance which it gives to the physical sciences arises out of the peculiar role which the physical sciences have been found to play in the last 20 years in matters involving national defense?

Dr. HOLLOMAN. In matters involving national defense—and health which it doesn't support—and the space effort, I think that bias exists.

Mr. BROWN. Wasn't it true that in the 19th century when this country began to support the development of science through such roundabout ways as the founding of the land-grant colleges, that the basic effort was motivated at least in part by a need to solve a national problem which was in the area of food production and agricultural research?

Dr. HOLLOMON. That is correct.

Mr. BROWN. Doesn't this then lend support to your statement that we need today to look a little more broadly at the totality of the industrial, economic, and social problems that you have indicated, and to measure our support of basic science in a broader sense?

Dr. HOLLOMON. Yes, sir; the unfortunate thing about that is because of the way science is supported in this country, the likelihood of that happening, that is, people simply making proposals to NSF, is negligible. It would be like trying to start agricultural education through the land grant college by waiting for somebody to make a proposal from an institution that didn't exist.

Mr. BROWN. This is the point I have explored with several of the witnesses who have said that we are funding proposals in the social sciences in roughly the same proportion as we are in the physical sciences. This, of course, is the very point that you are making. We are not getting sufficient proposals in these areas because our basic research effort in the universities and colleges is not geared to the present needs of our Nation and our society. We need therefore to stimulate some activity beyond what we have at present, and what we are getting under the present proposal system.

Mr. DAVIS. Would the gentleman yield on that point?

Mr. BROWN. Certainly.

Mr. DAVIS. It strikes me, and perhaps both of you will agree, that our bias in favor of the physical sciences is probably far more deep seated than we realize. For example, the dramatic advances that were made in the 19th century—in the discovery of the microscope, in the discovery of the telescope, in the usage of electricity and in the ability to put combustion or heat to work in the form of a steam engine or an automobile—all of those were results in tinkering with the physical sciences.

I think that our bias in that connection, if you want to call it a bias, is quite old and quite deep seated. I concur with both of you in your recognition that it is a bias. We should devote as much time, thought, energy, and effort toward solving some of the problems in the behavioral sciences as we do in the physical sciences.

Dr. HOLLOMON. And particularly in cooperation, because the big problems that we have before us, as I see them—urban problems, the problems of pollution, the problems of transportation, the problems of the less developed countries—are problems that have two characteristics: one is that things and people interact strongly; and the other is that they are tremendously complicated. This says, it seems to me, that you want to do two things: one, try to get more effort where things and people interact, and second, people who have an

ability to deal with complicated systems. This matter was discussed by the committee earlier. I disagree a little with Mr. Vivian when he said that one can't distinguish between engineering sciences and physical sciences. The question is one of motivation. If we are trying to understand what goes on when people and freight are moved and we try to simulate the system and to understand it, we do it because the movement of people and freight are important to us. I would call these studies engineering science. Yet the science that has to do with moving people and freight is a generalized science. On the other hand we support the understanding of the universe, the galaxies, for example, because they are there and because we have faith that if we understand them we will be better off somehow.

Admittedly many times these two kinds of work are similar. One of the reasons why Congress and others think there is duplication, is because the actual work is hard to distinguish. But, I do believe there is a science which has to do with the things that undergird the economy, such as industrial production; simulation; transportation; communication; urban development; construction of houses; construction of buildings, et cetera.

Now my point is that this kind of science—call it what you will—or this kind of inquiry, is inadequately supported.

Mr. DAVIS. I agree thoroughly with that.

Mr. BROWN. By way of rebuttal to your very cogent point about the fact that our support of basic physical science today goes deeper than its significance to national defense, I think it is obvious that within the scientific community there has been a great deal of devotion to the physical sciences. This has, as you indicated, grown up in the last 50 or 100 years.

This has led to a fractionization of science, and a specialization in science which is characteristic of our society today. In other words, we have a scientific community which is growing more increasingly specialized, particularly in the physical sciences. I question, and this is a purely philosophical question, whether this is necessarily the best way for our society to go. I think this is the problem which is raised by Dr. Hollomon's paper.

I am one hundred percent in agreement with the statement which you make on page 11, that:

Today, as in the past, we need to support the science relevant to our needs.

Mr. CONABLE. Will the gentleman yield? When he says this goes deeper than you may realize, I believe he is correct. There is an element of American conservatism here relative to the function of the Federal Government.

No one can question the function of Government in national defense. However, someone can question the function of Government in designing a better home, because this sector has been traditionally taken care of by the private side of our economy. This has resulted, perhaps, in a reluctance to put ourselves into the fields of science which may have some possible danger in relationship of the Government to the individual, as for example, the behavioral sciences. There may be some reluctance based on essential American conservatism.

Dr. HOLLOMON. I believe that to be the case. I think you make a very important point, but I think that conservative bias does exist.

But, if we had a large number of young people at our universities who were concerned and thinking about the problems of building houses or buildings—I don't mean designing a specific one that you and I are going to buy—we all would profit. They would examine the problems of people, buildings, and cities in a complex society. This would seek ways to solve the system problem, the environment problem, and the noise problem. These are science questions.

Mr. CONABLE. The point is whether or not we have this sort of emotional reaction by getting into the behavioral sciences. Apparently there is no reluctance on the part of the Government to expand its role constantly. If this is the case, then certainly we have to find ways through science to expand its role intelligently.

Dr. HOLLOMON. Right. May I give you an example of this conservatism which I think illustrates the point. It is now possible and has been possible for some time to increase substantially our ability to simulate and predict the economy, either small or large. One of the big advantages in this is the so-called input-output analysis which has been developed over the last decade. Now, the amount of support for this kind of technical work—I don't known what you want to call it again—that is, to understand how one kind of competitive system operates is small. There are many people who feel that this understanding somehow threatens the enterprise system and invades the rights of the private sector.

As a consequence, the support during the last decade for this kind of work has not grown. The last input-output analysis tables that the Commerce Department has are based on the economy of 5 or 6 years ago. The amount of work which the National Science Foundation supports, to understand the economy is negligible compared to the amount of work it supports in solid state physics. Yet this is a perfectly respectable intellectual activity. It doesn't, in my view, invade the private decisionmaking process.

Mr. CONABLE. I am not disagreeing with you, but we have to go back to our constituents and justify the expenditure of their tax money for science. If we can relate the expenditures to the space race with Russia or to national defense, we find ourselves on a lot sounder ground with a basically conservative American people than we do when we start getting over into an area which could be described as Government tinkering. This is the way I would interpret Mr. Davis' remarks, and I think it is a fairly significant thing when we are considering what the role of the National Science Foundation should be. We obviously have an obligation to lead as well as simply to reflect the basic attitudes of our constituency.

Dr. HOLLOMON. I think there is one factor which may aid in this process, and that is if an increasing amount of the funds were provided for institutional support, as the tendency is now going, then these decisions as to what you do could be made locally by the institutions and the technical people themselves. This would give you a wider variety and scope of effort if it were done in that fashion.

I make another comment. I was in the Soviet Union about 4 or 5 months ago, and the only thing that I saw there with which I had some concern was the major effort that the Soviet Union began to make about a year ago and is now making, to put computer and analysis activity to work on decisionmaking and how their economy

functions. This is the only thing I saw which I believe they are really emphasizing and they are likely to do some things which we in this country are not doing. So even in this field there is competition with the Soviets.

Mr. BROWN. I think this may be a very important aspect to emphasize here. As you have indicated, it is the basic political problem with regard to support of science in this area. We have justified such ventures in absolutely pure science, such as space exploration, on the grounds of competition with the Soviet Union. I think it may be equally valid and perhaps far more important that we have successful competition with the Soviets in the understanding of economic systems. It seems likely the Soviets are moving in the direction of recognizing the vital importance of certain aspects of the market mechanics that we don't even understand ourselves. We assume as a matter of faith that the free market is the ideal mechanism for regulating the economy. It is not so much based upon analysis as it is on faith, and there are areas in which we have slid back a little bit, to say the least.

This line of discussion leads immediately to a significant question: Under these circumstances, is it necessarily true that the National Science Foundation is the best mechanism for encouraging this type of basic scientific research, if we may describe this area as being one of basic scientific research?

Dr. HOLLOMON. I think this area is like many others in that, for very specific reasons, the various mission-oriented agencies are going to have to do some work in this field because it is essential to their missions. In the case of water resources, for example, in which there is a very complicated economic, a simulation, an analysis, and a cost problem; the agencies responsible are going to do research which they deem necessary to deal with them. However, deeper questions are involved: I think a central core of support is needed to provide the freedom, not limited by the peculiar requirements of a particular mission-oriented agency. Here we are dealing with questions, in which the industry of America, particularly in the productive process, is deeply involved. I think it is important that we do not support work which is the primary domain of a particular company, a particular product, or a particular market. A small amount relative to the whole ought to be supported, particularly in universities, to attract the attention of some of our brighter young people to these fields which, I think in the long term, are just as important as the science of chemistry, physics, biology, and mathematics.

Mr. BROWN. Purely by historical accident we have a situation where the basic health sciences, and this includes biology and medicine, are supported primarily by the National Institutes of Health. In the last 15 years, stemming from the impetus of the wartime discoveries in physics and so forth, we created the National Science Foundation, which has a "balance wheel" function in this area. What we are talking about here is sufficiently different in scope and approach that it might be desirable to start another agency whose focus would be on the relationship between science and people.

Dr. HOLLOMON. And the economy.

Mr. BROWN. And the economy.

Dr. HOLLOMON. That may well be the case. I think it presents to this committee and the Congress a very real question. Should the predominant role in this area be that of the National Science Foundation or is there need for a new kind of activity in some other agency? This requires deep consideration and thought. I believe the need is real, and it is particularly important as we look at the next 10 years or so. Unless we get at the research now, we will not be in a good position to deal with these increasingly complicated problems in the future. This committee and the Congress, in its deliberations ought to come to grips with the question of the means by which we begin.

Mr. BROWN. It might help solve the political problem, involving the desirability of governmental support of this area of basic research, to have this in a separate agency. The policy could be debated and resolved by this agency and we could look back and review how we, for instance, got into the basic support of agricultural research when agriculture is an excellent example of the free enterprise system. This program initially developed in the 19th century. If we could see the comparison between today's problems and the problems of a hundred years ago and generate the political support that would be desired, we might be in a position to move ahead much more rapidly than we have been in this area.

Dr. HOLLOMON. In agriculture the science is supported by the Agriculture Department and not by NIH or by NSF. Three things were done there: No. 1, and I think the most important, was the establishment of the land-grant colleges. Second, was the establishment of support for research at the universities, associated largely with the land-grant colleges. Third, was the development of an extension program to translate and to connect that research to the people who had to use it. I think we need all three steps to meet the modern industrial, social, and economic problems of our time. We should first establish new institutions throughout the entire country to continue to develop people and industry.

Second, we need the support for research in these fields which we have been discussing by proper mechanisms.

Third, to insure the proper means of connecting that research to the recipients, the people, the Government, the industry, by an extension type activity. A program to meet the third need as you know, Mr. Brown, is now before the House. The purpose of the State Technical Service Act is to connect the basic research in universities to industry in a way that will not interfere with private enterprise.

Mr. DAVIS. May I add one thought to what you have just said about agriculture. I think that probably the greatest accomplishment that the extension program made was selling the farmers the idea that "what was good for papa is good enough for me" is not the correct attitude. Traditionally that has been the peasant attitude in the European countries since they quit hunting animals and started raising food to gain their subsistence. Farming people have had a tremendous resistance to change throughout the history of civilization. I think the extension course is what overcame the prejudice and this basic resistance and made it fashionable for a farmer to seek the latest

innovation in farming. I would not be surprised if that isn't the one huge difference between the American farmer and the Russian farmer today.

Dr. HOLLOMON. I couldn't agree with you more. The proposal that the President has made with respect to the use of science and technology in industry throughout the country called the State Technical Service Act, now before the House and the Senate, is, I believe, a most important step with respect to this problem. It relates to the problem of Midwest industry versus the industry of the two coasts. It hopefully will aid in convincing people that we can have a free enterprise industrial system and still have it change and be adaptable to change. Hopefully, it will allow better use of the University of Illinois in Urbana or the University of Michigan, for example, to bring to the community the new things that industry requires to be alert and alive. It is the single most important thing to do, in my view and that is why I hope that the Congress will, in this session, act favorably on this particular legislation.

Mr. BROWN. I have no further questions.

Mr. ROUSH. Mr. Conable?

Mr. CONABLE. No questions.

Mr. ROUSH. Mr. Vivian?

Mr. VIVIAN. I have a series of questions, but I would first like to make a comment regarding agriculture.

Agriculture generally serves a very large number of competitors, such a large number that no one feels he is getting any particular advantage or disadvantage, whereas research done for industry often serves a very limited number of very large concerns, and these concerns represent a small number of voters but a much larger amount of economic pressure. I think there is quite a distinction to be made between supporting agricultural research and industrial research, even though I am in favor of supporting industrial research.

Dr. HOLLOMON. May I interpose?

Mr. VIVIAN. Yes.

Dr. HOLLOMON. You are quite correct about the small number of large firms in manufacturing, but increasingly manufacturing is a smaller part of the American economy. The largest part of our economy is the service industries. These are the stores, the shops that repair things, and the enterprises that provide us with all sorts of services. These industries are often small, locally oriented. They engage, as you are well aware, the larger number of workers in America. More than half, now works in those industries which tend to be small and noncompetitive in the sense that they are local and regional. The service firm in California isn't competing with the maintenance man in the city of New York. They are noncompetitive in that sense, while they are very competitive locally. I think you are quite right about manufacturing, but I don't think your statement is fully correct about the service industry.

Mr. VIVIAN. I am sure you are correct.

That would suggest some of the activities in your own Department might lean toward the service function?

Dr. HOLLOMON. Without any question.

Mr. VIVIAN. You commented on the relationship between NSF and the National Center for Atmospheric Research. That may have

been discussed while I stepped out of the room. Was it discussed at any length?

Dr. HOLLOMON. Briefly.

Mr. VIVIAN. I would like to know where it is located.

Dr. HOLLOMON. Boulder, Colo.

Mr. VIVIAN. Is it involved in the proposed reorganization within the Department of Commerce for the environmental sciences?

Dr. HOLLOMON. No, sir.

Mr. VIVIAN. It is not involved?

Dr. HOLLOMON. No, sir.

Mr. VIVIAN. It is strictly concerned with research in the atmosphere?

Dr. HOLLOMON. Yes, sir.

Mr. VIVIAN. In what obvious way would it not have close relationship to this grouping of the environmental sciences?

Dr. HOLLOMON. It has a very close relationship. I have to be very careful about that question: In what way would it not. It does have a close relation and it should have an increasingly close relation.

Mr. VIVIAN. In other words, someone not aware of the potential battles between bureaus might have concluded that it should have gone under that proposed grouping?

Dr. HOLLOMON. I am certainly not in a position to answer that question either way.

Mr. VIVIAN. Are you indicating that you feel that this organization in a sense competes for NSF funds from outside proposals?

Dr. HOLLOMON. It may tend to.

Mr. VIVIAN. Are there proposals being funded from outside which are directly parallel to this Center's activities?

Dr. HOLLOMON. No; I think you misunderstood. Let me make my thoughts clear. What I said was that the NSF completely supports NCAR, and it also supports atmospheric sciences at the universities. Since it does give complete support to NCAR I think it would, without question, feel responsible for seeing that it is in good shape. In that sense NCAR competes with proposals that come from other institutions in atmospheric sciences, of which there is a fair amount.

Mr. VIVIAN. At least there is a fair amount outside now?

Dr. HOLLOMON. Oh, yes.

Mr. VIVIAN. Is the present situation criticizable?

Dr. HOLLOMON. Not necessarily.

Mr. VIVIAN. You indicate that NSF should not take on responsibility for applying knowledge and for operating development programs, except in the fields of education and science information. I presume you included in that such things as Project Mohole and weather modification?

Dr. HOLLOMON. I have not followed the Mohole project carefully. I limited it to my own experience, I refer specifically in cases to which I have experience. I raised the question of weather modification.

I would like to defer on the question of Mohole, but I think that the National Science Foundation by the very nature of things, should continue in the role of a granting and not as an operating agency.

Mr. VIVIAN. What is the exact label for this environmental science grouping? It is not a department.

Dr. HOLLOMON. It is an administration, with a long name which we will from now on refer to as ESSA.

Mr. VIVIAN. Would that administration be a fairly logical place for the Mohole project?

Dr. HOLLOMON. I don't think I can answer that.

Mr. VIVIAN. Perhaps you would like to think that over and discuss it at a later time? On page 7, you mention the weather program. I understand the Weather Bureau has certain responsibilities, as does the armed services and NASA. I do not construe the National Science Foundation as having a major responsibility for the overall coordination of the weather program.

Dr. HOLLOMON. Right.

Mr. VIVIAN. It would seem then that they have in a sense a peripheral role as measured by dollar investment.

Dr. HOLLOMON. Not in research. Their role in research support for meteorology broadly is not peripheral, it is significant. It is larger than that of the Weather Bureau.

Mr. VIVIAN. Does the Weather Bureau have less money invested in research?

Dr. HOLLOMON. In research, yes.

Mr. VIVIAN. Do NASA and DOD have less money invested in research?

Dr. HOLLOMON. The NASA situation is complicated, as you know, by the high cost of equipment.

Mr. VIVIAN. I understand that problem.

Dr. HOLLOMON. The National Science Foundation support for meteorological research was in 1966 about $15 million per year. This support is for meteorology alone, not all atmospheric sciences. It does not include aeronomy. The Department of Defense's total was $12.8 million, and the Weather Bureau in that field was about $11 million. So the largest single supporter outside of NASA, and I will come back to that in a minute, in 1966 is the National Science Foundation. The smallest of those four agencies supporting research was the Weather Bureau. Now, NASA's large costs are because of the high hardware costs of satellite development, but it is by far and away the largest in terms of money support in research and development in meteorology.

Mr. ROUSH. Mr. Vivian, Dr. Hollomon has a 12 o'clock appointment, and we agreed to let him go as soon as possible after a quarter to that hour.

Mr. VIVIAN. Let me see if I have any other matters which I think are absolutely essential here at the moment. Yes, I want to bring up one question, and that is as follows: Do you feel that there is any possibility that through either the program which you have before Congress now or others, it will be possible to lease Federal facilities for industrial research? There are many Federal facilities which contain tremendous capital investment. The utilization varies at times from heavy to light. Has any consideration been given to leasing these facilities?

Dr. HOLLOMON. I know of no such considerations. There are no bills before Congress that I know of with which I have contact. We do have, however, one program, which we are trying to increase, at the National Bureau of Standards, particularly when it moves to its

new site in Gaithersburg. We are increasing what we call our research associate program in which an industry can put people physically on the site by joint agreement between the National Bureau of Standards and the industry. We now have about 30 such industrial associates. There are certain terms and conditions under which this is done, but essentially the industry, which does not have its own facilities, is able to utilize the NSF facilities under terms which we believe are in the public interest.

Mr. VIVIAN. I believe AEC has made the type of arrangement for dealing with nuclear materials. I would appreciate it if you could give me some information as to where industrial firms or nonprofit organizations are allowed to use Government facilities.

Dr. HOLLOMON. I will try to do that.

(Dr. Hollomon's reply, in a letter addressed to Mr. iVvian, will appear in the appendix, "Communications to the Subcommittee," of volume II of these hearings.)

Mr. ROUSH. Mr. Yeager.

Mr. YEAGER. I have a number of questions, Mr. Chairman. I would like permission to submit these to Dr. Hollomon and ask him to supply the answers for the record.[1] I would also like to submit some questions to Dr. Kinzel who appeared earlier, if that is agreeable.

Mr. ROUSH. It is agreeable with the committee.

The committee stands adjourned until July 20.

(Whereupon, at 11:55 a.m., the subcommittee was adjourned to reconvene Tuesday, July 20, 1965.)

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, JULY 20, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. The meeting will come to order.

Our first witness this morning is Dr. Pendleton Herring, who is the president of the Social Science Research Council. We are pleased to have you here, Dr. Herring. Will you please proceed?

STATEMENT OF DR. PENDLETON HERRING, PRESIDENT, SOCIAL SCIENCE RESEARCH COUNCIL

Dr. Herring. Mr. Chairman, I am delighted to have this opportunity to present some comments and reflections to the committee. I don't come prepared with facts and figures to present at length, but I thought it might be helpful to talk informally on the basis of my observations and contacts with the problems of the social sciences and governmental relations over the years.

I think it might be most useful if I indicate first to the committee the four or five topics I have in mind to touch upon, and there might be questions that you may have on each of these topics as I go ahead. I would like, first, to say a few words about the social science program as I have observed it in the National Science Foundation.

I have been chairman of an advisory committee concerned with that work in the Foundation, and that has given me some occasion for following the activities there. The second topic I would like to touch upon is the broader view of social science research and the Government. There are aspects that I think are quite pertinent and give us a better sense of proportion and background as we view these problems.

The third point is how to get more stable support for social science research. It seems to me that is a very basic problem.

The fourth point is how more effectively to represent the social sciences, to get their viewpoint understood and expressed in policies that relate to these fields.

And finally, perhaps if there is time, a few remarks about the broader basis that is needed, and the significance of these fields as we look to the future, the contribution that they can make both nationally and internationally.

If that is agreeable to you, Mr. Chairman, and the committee, I will proceed in this fashion.

As I thought about appearing here informally this morning, a conversation came back to memory that took place when I was in Paris a year ago in January. I found myself at an agreeable restaurant talking to the chief official of the French Government concerned with cultural relations with Africa, and in the course of the conversation he said: "You know what we have to offer to the Africans is French; it as the key to French culture." If you have ever seen an African who has a complete command of the French language, you know what he is talking about. It is a vivid experience.

I said: "What do we have in the United States to offer these developing countries?"

And his response surprised me: "You have the social sciences."

Nobody ever said that to me in Washington. I mention it here because I think it indicates one or two things, whether you agree with the statement or not, it has this factual basis: That there is a recognition in other parts of the world that these fields are highly developed in this country and that we have something that they would like to have more of. The other factual point is that if the developing countries of the world are to develop, if they are to have a command of their economic problems and their social problems, the wilderness of human problems which they face, and must face rationally if they are to get anywhere, then they need the skills that are represented by these disciplines.

I just recount that anecdote as indicative of an atmosphere.

Let's turn back very briefly to the atmosphere when the National Science Foundation legislation was under consideration. I know you have all the facts and ample Government documentation on that, so I will offer a few personal impressions. I remember the meetings here in Washington of various of us who were interested in that legislation; the debate that took place between those who wanted to get on very much with support for science, and the effort made to present a coherent and more or less united opinion to the Congress in 1947. At that time an intersociety committee composed of 2 representatives from each of 75 learned societies where canvassed for their opinion and only 2 percent of that group felt that the National Science Foundation should be limited to the natural sciences, 49 percent thought that the social sciences should be included, and the other 49 percent took the permissive attitude that they might be included if the agency wished to do so.

Well, I cite this because it indicates that there was a pretty flexible situation at the very beginning. But by the time the agency was established—and you have the legislative history and you recall the terms of the act—by the time the agency got underway and came down here to seek its appropriations and began to adjust itself to the competing agencies in the field of science the "atmosphere" had changed a bit. You remember there is some reference to "coordination in the act," what implications did that have in terms of interagency relations. That is always a little bit of uncertainty when one agency undertakes to coordinate another agency. In other words, there was a certain tentativeness, a certain, dare I say, nervousness about what the future development of this agency was to be. And

what I say about the National Science Foundation in these early years, gentlemen, I say not in any spirit of criticism at all but rather as a commentary on our life and times, a commentary on the spirit of the 1950's and the problems that were being faced.

Well, what happened with respect to the social sciences? Nothing at first. It was some time before anyone was put on the payroll to deal with these fields. Very tentatively it was decided that while there was no distinct organizational unit for the social sciences, grants might be made in so-called convergent fields, that is to say that if either the biological and medical sciences or the mathematical, physical, and engineering science divisions had something that had a connection with the social science field, they might lend some support. It wasn't until 1956 that a program was created within the National Science Foundation, and it wasn't until 1958 that an Office of Social Science was established.

Well, by 1958, mind you, there were three people there, and in that year they made 49 grants. After 8 years, 3 people, 49 grants, and then sputnik happened, and something happened not only to this little Division in its basement offices in the NSF but something happened to the United States of America, and as you look back over those years at this midpoint in the NSF you see that it really was an awakening and in the aftermath of this realization, the junior partner, the social science activities in the NSF, began to take on a greater stature and importance. If you will excuse the informal irony, I am tempted to report that in those earlier days we used to say to one another, well, this program is concerned with the basic aspects of the social sciences, but, of course, we must keep away from race, religion, sex, and politics. We can hang our clothes on the hickory limb of science, but keep out of the mainstream of social problems. I apologize for the irony, but that reflects a bit the attitude of some of us who watched from the sidelines and wondered really was this getting on with the job.

I cite here a paragraph or two of a background paper prepared in 1960 when the Division of the Social Sciences was finally created within NSF:

When the Foundation began support of the social sciences the scope of the program was small and its emphases were not those which social sciences themselves would have chosen. Many therefore felt that the Foundation was giving scant and unsympathetic attention to their needs and was merely paying lip-service to the whole subject.

This opinion changed somewhat. These evidences of the Foundation's good faith and the durability of its intentions as well as the steadfastness with which the NSF has hewed to the line of basic sciences has had some desirable effects on the social science community.

In the first place this increased recognition has encouraged more established, prominent, and reputable social scientists to apply to NSF. Evidently they have begun to feel that the Foundation is genuinely interested in assisting in the study of social science problems and the development of research techniques, and many no longer feel it is idle or pride-risky to apply to NSF for assistance.

The second good effect of the Foundation's stance has been to demonstrate that it really means to support basic research and the development of social science rather than applied craftsmanship in social affairs or contributions to topical concerns with important social problems. In the past, many capable investigators had hesitated to invest their energies and to stake their careers in the pursuit of basic research because of the uncertainty of its support and sometimes whimsical changes in fashionable topics supported by fund-granting organizations.

I think you may catch from my emphasis, gentlemen, there is a little more in that official statement than meets the eye. It was a matter of gaining the interests and competence of the leading people in these social science fields. They didn't have to go to NSF for support, there were other channels, and it was in part a question of their status within the organization.

This was a very important if somewhat subtle consideration. One cannot gainsay the fact that these fields have been the "junior partner," and this is a matter that I think has relevance for the future, and I will come back to it later.

I do not want to create the impression that there wasn't a friendly atmosphere, particularly with the establishment of the Social Science Division. There was a growing realization within the Foundation that these fields were important and that they had a place and the creation of the Division put them on all fours organizationally with the other activities. The staff has been a devoted staff and its members have won an appreciation and understanding among their colleagues in the other divisions, often in my opinion through the sheer force of their ability, their personality, their being good members of the NSF team. While there were discouraging elements in characteristics of the beginning period, I want to emphasize that within the NSF in the last few years the curve of increased support has been the steepest curve.

If you just look back, over the appropriations, let's say the grants activated and approved since 1960, 1961 to 1965, the curve goes up each year as follows: 2 million-plus, nearly 4 million, over 7½ million, nearly 9 million, over 9 million, and in 1965 well over 10 million. So in terms of the rate of increase it has been sharp. In terms of relative support, of course, it is a very modest percentage.

That, I think, Mr. Chairman, reviews the main points I had in mind about the program within the National Science Foundation.

Mr. DADDARIO. We are pleased to have the chairman of the full committeed here with us this morning, Dr. Herring: Chairman George Miller.

Mr. Chairman, do you have any questions?

Mr. MILLER. Doctor, I want to thank you for coming here. I think that you have given us some provocative statements that will bear some thought and contribute to our examination of the National Science Foundation.

I have been concerned about the social sciences and the humanities. In this country. we can't afford to neglect these things.

Of course, being a product of the old scholastic system of education, I have always thought that education was a matter of trying to teach men to think, and that if we get him thinking, he can do a pretty good job for us.

Thank you, Mr. Chairman.

Mr. DADDARIO. Thank you, Mr. Chairman.

Dr. Herring, you say the curve of support for social sciences has gone up, but then you say that the percentage is, however, modest.

I wonder if you might analyze that a little bit further. What do you think the percentage ought to be? What shall we, as a congressional committee, be thinking about in this regard?

Dr. HERRING. Mr. Chairman, I think I could be most responsive to that if I sketched in a bit this broader picture. Would that be acceptable to you?

Mr. DADDARIO. That would be fine.

Dr. HERRING. So I wouldn't get too much concerned with detail with respect to the facts and figures on this program.

Mr. DADDARIO. Don't worry about that.

Dr. HERRING. But to respond to your broader question. I would like to say as my second point that the Federal Government is one of the very great consumers of social science talent, just historically viewed. You couldn't run the Government without economists and statisticians, labor economists, agricultural economists, experts in monetary affairs, experts in international trade, and so forth. So that point needn't be elaborated, it is perfectly obvious.

The consumption of the talent of psychologists, clinical psychologists, is essential in the work of the Veterans' Administration. There is an enormous consumption of those skills there. Our Public Health Service draws upon them, also.

The conduct of international relations, the advance of public administration, all that the universities have done to make men think, Mr. Chairman, in these fields are reflected back in the work of the Government. I don't believe any of us would argue that point. But the point in my mentioning it is to contrast the consumption of these skills with the input: What has the Government been putting into these fields? And there we come back to your basic question, Mr. Chairman, as to what has been the nature of this input.

In dollar terms, as we know from the excellent tables that have been submitted to the committee, the percentage, as we have said, is modest in relative terms. In absolute terms there have been very substantial sums of Federal money directed to these fields.

If I had the time and assistance it might be in point to look back over the actual dollar expenditures and see what those dollars went for, and I would wager that from direct experiences I have on a few occasions there has been too much money available too fast and cut off too soon. It has been a pattern of hit and run. It has been a pattern predominantly I would suggest, and here again you can check on this, but I would suggest that the largest expenditures have been in connection with mission-oriented agencies where support in social science research has been a byproduct.

I hope the committee will address its consideration to this phenomenon of mission-oriented work that as a byproduct undertakes to support basic research. I won't attempt to comment on that. In the natural sciences you can get specialists there who know about it. But when it comes to the social sciences, ever now and again you pick up the newspaper and what you are really reading about is the consequence of this kind of administration. I don't want to press that unduly. It is a problem facing the State Department and the Defense Department right now in connection with the Project Camelot, and I don't feel competent to go into that in any detail, but it is another one of these illustrations.

In the course of my years in Washington I have served in the past as a consultant to the Army, the Navy, the Air Force. I have worked

with the Budget Bureau and have been close to the National Science Foundation, and one sees there this phenomenon that I think has received inadequate attention. That is one part of this problem of how to get stable support.

In other words, in answer to your question again, Mr. Chairman, I think that it isn't the absolute sum, it is the purpose. It isn't the absolute sum, it is the conditions under which the grants are made, it is the lack of continuity, and it is the spirit in which the support is offered. And the spirit that needs to infuse these activities is the spirit of treating them as needing developmental support.

Maybe one way to bring the point rather forcibly before you would be to say that the problem in these terms is on all fours with the problem in the natural sciences.

I think that in this excellent volume prepared for the committee, "Basic Research and National Goals," there is a magnificent statement in here by Roger Ravel on the earth sciences in the Federal Government, and let me just take one paragraph and just change the references from "earth sciences" to "social sciences," and you will have the story:

> The greatest need in the social sciences is to maintain and develop centers of excellence in our universities. This can best be accomplished through university centers of teaching and basic research where social scientists and students can work together in close contact with each other and with the fundamental disciplines of economics, sociology, anthropology, political science, statistics, et cetera, and where the interplay of teaching and research can stimulate both. By underwriting the vigor and dynamism of many such centers it will increase the likelihood that new ideas and fresh viewpoints can arise.

The relationship between what we do down here and what happens back on the campuses, what happens in Ann Arbor and what happens in UCLA and what happens in Berkeley and what happens in the great universities over the country is direct and, well, I hesitate to say so, but almost determining. The distinction between public and private universities, if you look at it in financial terms, is a pretty meager distinction, and you may have some witnesses who can develop that at great length.

Well, let me conclude this point, Mr. Chairman, by saying that I think the practice of subsuming under missions and other guises support for the social sciences has certain consequences that could be further examined. There is a reason for this. I understand the reason very well indeed, and I wouldn't want, shall we say, all the protective covering to be stripped away by unfriendly hands.

But if you look across the board, you see that the National Aeronautics and Space Administration and the Department of Defense have very large sums, and some of it helps these fields; you see that excellent work has been done by an agency that we regard in the highest esteem, the Office of Naval Research, that has done wonderfully well in supporting basic work; the National Institutes of Health and the National Institute of Mental Health have contributed to these fields; but I hope the day may come when it will be possible to call things by their right names and not have to relate research in sociology, let's say, to some aspect of mental health.

Maybe the day is coming when we can take pride in the social sciences, when we can say this is a national asset, this is something that

has been developed in this country as in no other country, and we like it and we want to support it, as social science research.

May I elaborate on that just a bit?

Mr. DADDARIO. Surely.

Dr. HERRING. I thing it is a magnificent story when you consider by contrast the story of our development of these fields and the sad story across the sea. If you look back to the 19th century, you see some towering figures in social science, some great men stand forth, but why were those great men's influence, why wasn't that carried forward into this century? Whatever happened in Europe as far as Weber, Durkheim, and Pareto and the whole school of provocative thinkers about social problems?

For one thing, European universities have been and still are so tradition bound that it is exceedingly difficult to get support for new fields. I could go into that further. Changes are underway; there are exciting developments in Great Britain in relation to these disciplines but by and large the weight of tradition in European universities has held back these fields.

Now the reverse of the situation in the United States: Our universities have been experimental, they have been empirical in their approach. If the community needed something, they were there to provide it, and they could make men think about all sorts of things. If they had to think about the most mundane things, they thought about it, and they came up with ways of dealing with them. That is what has happened, of course, in the social sciences. So we have this contrast.

Another contrast, of course, is the impact of the war on European countries and greatest of all the impact of dictatorship. We benefited, of course, by the highly intelligent men who came, ousted by the dictators of Europe, and many of them were in these fields, so we were enriched by that.

But above all we have been encouraged and carried forward by the freedom to discuss and to criticize and to comment and to suggest and to experiment, not only in the natural sciences but in these fields also. So there has been a very interesting relationship between the needs of the country and what has happened in these social science fields, just as well as in the natural sciences.

For example, the depression focused men's attention on economic phenomena—there was a stirring up of thought and a response within our universities. I think back to the days at Harvard when I was surrounded by Keynesians and listened to that discourse. Like it or not, there was a stimulation to economic thought that now these many years later I think you will agree is bearing some pretty substantial fruit. That is one aspect.

Another aspect is to be seen toward the end of President Hoover's administration and his concern with social trends and the engineering approach very broadly applied. His support for the study of social trends that emerged in that great set of volumes is an illustration. With the coming of the New Deal and with the necessity of building up a more adequate administrative service, there was a concomitant interest in our universities in training for public administration.

I was in the thick of that because I was secretary for the first decade at Harvard in the Graduate School of Public Administration where we were trying to get on with the training of men for public service.

There was a wonderful spirit on the part of the Government and on the part of the academic world in getting on with that particular field.

After World War II, another illustration, as we realized that we were part of a larger world, the necessity for understanding new parts of the world became evident, and that was reflected very quickly in the development of so-called area programs in our universities.

In the Social Science Research Council, we took an active lead in bringing together people in the universities and working with the private foundations in encouraging the study whatever needed to be studied about major areas of the world. In those days one of the things that needed attention, and needed it badly, was the Soviet Union, and there were some social scientists bold enough to want to find out what the Russians were doing and how Russia is ruled, despite the fact that in those benighted days some people thought even to take an interest in the Communist world was a somewhat questionable undertaking.

Well, I could go on at great length, but the point I would like to register with the committee is the relative rapidity with which you can win a response in these fields. For example, Africa was indeed a Dark Continent as far as this country was concerned in 1947, but where there is a sense of purpose and destination and reasonable financial support and national need, you can win a response with relative speed if you keep at it steadily.

I mean by "relative speed," say, 10 years. What is 10 years in areas as important as this? Indeed, it seems a little ironic that the number of people now interested in Africa almost threatens to be an embarrassment of riches because there is a limit to the number of African officials available to talk to the many specialists that turn up over there from the "developed" countries. Leaving that point aside, the fact is that we have extraordinary human resources, we have in the United States an academic community and university system that is responsive and responsible when it comes to meeting opportunities to serve the Nation.

Mr. Chairman, that is the third point I had in mind. The other point I would like to go on with raises the question of how to provide for a representation of social science needs. If you would like me to continue with that, I will do so.

Mr. DADDARIO. Please.

Dr. HERRING. I think this is a very relevant problem area for the committee. What pattern is most appropriate for insuring representation of the social sciences? If you call it a pattern, the present situation is rather kaleidoscopic. You see a variety of agencies, a variety of sources of funds, a variety of motivations, a variety of policies and occupations, and, except for the NSF and one or two other exceptions perhaps, it is very difficult to clearly envisage the relationship between the social sciences and the Federal Establishment.

Now the National Science Foundation has the charge to foster basic research. They have been supporting the social sciences, they have broadened their coverage recently so they have taken in political science as still another discipline, and one way to envisage the future would be to say, all right, let's broaden the base within the National Science Foundation still further. I know there is a friendly attitude

on the part of those running the organization, and a broadening of NSF jurisdiction is a distinct possibility to keep in mind. It does mean that what I refer to as the "junior partner" relationship is present.

One doesn't want to overstress it, but it is a part of that picture. By way of contrast, and here I am just contrasting, I am not recommending, but by way of contrast, let me present to you something that I find of great interest. Here is the report of the Committee on Social Studies under the chairmanship of Lord Heyworth, the report presented to Parliament by the Secretary of State for Education and Science, by the command of Her Majesty, June 1965. It has been very interesting to be in touch with Lord Heyworth and his staff about this development. The British, as I say, have muddled along characteristically and have been very slow to do anything about these fields. But now in this present report they refer back to the so-called Clapham Committee of 10 years or more ago where there was a fear if anything was done in these fields it would lead to the establishment of "spurious orthodoxes," whatever they are. So now they take a fresh look at the situation and they come up with the finding that the overwhelming majority of both senior and junior social scientists are strongly in favor of a Social Science Research Council in Great Britain.

They note there are contract funds for many kinds of research, and that normal support can go along through the university grants committee, and that there are ways of supporting in routine fashion, in Great Britain work in these fields. But the interesting thing is that this committee, under the chairmanship, as I say, of Lord Heyworth, an industrialist, a man of affairs, a broad-gage business-statesman, in the view of his committee the problem isn't one of routine support, it is to encourage new ideas and methods and to back men of promise. It is not to accept existing ways of doing things. They hope that existing funds will go on as usual, but they envisage, as they say in this report, the responsibilities of the Social Science Research Council to be as follows: first, to provide for support for research in the social sciences, second, to keep under review the state of research in the social sciences, third, to advise the Government on the needs of social science research, fourth, to keep under review the supply of trained research workers and to contribute resources toward this training, fifth, to give special consideration to the application of research in the social sciences, and to the dissemination about research projected and completed, and sixth, to give advice to the users of research in Government, local government, industry, and so forth.

Well, I submit that is an interesting statement. I wasn't quite prepared to have the Heyworth Committee come up with anything quite so, shall I say, so dynamic. They are not satisfied with things as they are and they are pointing in a new direction.

Well, I think there is enough in development in Great Britain to give one pause and to say: "Well, what is the best way in the United States to get on with the support of these fields and to try to realize their full potentiality? Are you satisfied with their status as a kind of junior partner?" It is very pertinent to raise that question, because the Congress now has before it a bill dealing with the creation of a Foundation for the Humanities and the Arts, and there are some aspects of the social sciences that are rather closely related to the humani-

ties. Some historians regard themselves as humanists, some as social scientists. You can't draw hard and fast lines through any of these fields of learning. They always overlap. So it raises a question of public policy as to how the Government should relate its interest, its concern, its investment in these fields to this seamless web of scholarship and research. Well, I have one point that seems to me basic and that I would like to place before you. I don't come here with a blueprint, but I want to make this basic point, that with the responsibility now, that the Federal Government has assumed in supporting education and supporting research and supporting science, it would seem to me quite desirable to have a reasonably clear relationship between whatever publics you are supporting and the governmental administrative pattern that you may be setting up.

For example, the Office of Education is receiving, of course, enlarged responsibilities and substantially enlarged appropriations.

Query: Should that agency, with its enormously important responsibility for dealing with primary and secondary education, and with the variety of things it is now assuming in the higher levels of education, should that cover the whole area or how are you going to divide it up? My plea would be that we try to think of a pattern of organization on the part of the Federal Government that would be responsive to the highest levels of research, the highest levels of excellence in scholarship and science, and try to see that Federal pattern in relationship to our universities and colleges. You are dealing with different publics when you are dealing with the highest ranges of advanced training and the frontiers of inquiry, whether it is in the humanities, the social sciences, or the natural sciences. You are dealing with subleties and characteristics there that are terribly important if you are really trying to encourage the specialists in these varied disciplines. And you are dealing with another set of problems when you are looking at our schools and all the vast difficulties related to getting on in that area. I do feel that it is desirable and might very well be possible to get a better fit between these different ranges of activity.

Now, at the present time where should a voice for the social sciences be heard? I wish I knew the answer to that. It has been suggested, for example, that on the President's Science Advisory Committee there ought to be a social scientist or two. I would like to second that suggestion. I would like to see what might be done that would be useful there. I have sat with at least one panel of the President's Science Advisory Committee and was very much impressed with the close attention and the sophistication of leading scientists when it comes to questions of public policy and their readiness to really address themselves to those problems.

I think a closer relationship at that level might be useful, at least to experiment with. When it comes to the Board of the National Science Foundation, it seems to me that, if the Science Foundation is to continue, as it presumably will, with supporting the social sciences, there should be social scientists on that Board. When I say social scientists, I don't mean a college president, I don't mean someone who was a dean in the past or someone who had some indirect interest, I mean someone who is a leader in one of the disciplines. I know that creates problems of just how many you can have in a board of that sort

and so on. I don't have any easy answer there. But I do want to underscore the importance of having people with a background in these fields on the jury when the decision is made as to "who gets what," because, as you know, many decisions relating to financial matters and to research directions are made in administrative committee meetings, and there ought to be someone present who can speak for the social sciences, lest by inadvertence or for no unfriendly reason that voice isn't heard.

Mr. Chairman, I don't want to belabor the point. I think I have indicated that I think there is a problem. It doesn't admit of a terribly easy answer, but I think there are various ways in which it might be investigated further.

Mr. MOSHER. Mr. Chairman.

Mr. DADDARIO. Mr. Mosher.

Mr. MOSHER. Dr. Herring, as a lay person, I must admit I am confused concerning the extent to which the scientific method can be applied in the social sciences, and to which of the areas of the social science it can be best applied. Has the National Science Foundation in making its selection for funding social science projects used that measure as a criteria? Has it tended to select those social science projects which most obviously lend themselves to the scientific method?

Dr. HERRING. Well, the selection procedure is through screening committees. Those screening committees are composed of highly competent specialists in the respective disciplines, whether they are natural science or social science disciplines. And the judgments that are made are the judgments of those individuals who sit on those committees and make their recommendations to the officials within the agency. In other words, it is a judgment reflecting the state of the field and the opinion of a man's peers concerning the significance of his work. Now, Congressman Mosher, I respond to your question in those terms, because if one begins to try to make fine definitional distinctions, as to how scientific is this as over against that, you could become involved in a debate some aspects of it metaphysical and some semantic, that lead to questions that are unresolved now and are not likely to be clearly resolved. But if you want me to give a quick answer to your question, I would say, by and large, "Yes, they do."

Mr. MOSHER. Do you think that the research that has been done under the National Science Foundation grants is the type of research that can be confirmed by other researchers? Is this experimental in its nature, quantitative, or to what degree is it only subjective?

Dr. HERRING. I commend to your attention the excellent paper in the report to this committee by Pfaffmann, who is a social scientist. It is a very thoughtful statement and one that I found to be very interesting reading. I would say in the social sciences when it is possible to identify a question that can be answered or explored by the use of quantification, the normal practice is to proceed in that fashion. There are matters that are not susceptible to ready quantification and it would be a waste of time to attempt to do so. Certainly the spirit of the social scientist today is to be detached, analytical, objective, and to quantify when he can quantify. Gad, if you could see the interest in using computers, you would sometimes think that maybe some of our brethren had gone too far in quantifying.

Certainly, the tendency is to seek the objective and analytical line.

Mr. MOSHER. The work done by the National Science Foundation in the social science areas has been good work in your opinion?

Dr. HERRING. Yes; I think so, and generally on the side that we have just been talking about. That is the research direction they are interested in, and that is the predominant direction I would say of the social science, if you can analyze such a general group. That is the direction, yes.

Mr. DADDARIO. Mr. Roush?

Mr. ROUSH. No questions.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. No questions.

Mr. DADDARIO. Mr. Davis?

Mr. DAVIS. Dr. Herring, you pointed out what dramatic results can be obtained from efforts in a given field once the need was perceived and accepted, and once a large group of people tried to solve the problems. You gave as an example the need for economic research during the depression. How widely accepted in your opinion should the need be before you can hope for results? Are you speaking in terms of a broad consensus of acceptance by the public?

Dr. HERRING. Well, that certainly helps as a background. No, it doesn't require a broad consensus, it requires a sense of conviction, a sense of direction. If you take, for example the National Bureau of Economic Research as an illustration, there was a research bureau set up through the dedication and vision of Wesley Mitchell, who devoted his life to the study of the business cycle as an empirical inquiry: What is this thing that comes upon us at intervals like a flood and destroys all things before it? Isn't there someway in which you can get men to think about that? So he tried to get men to think about it by collecting all the statistics and all the indexes and exploring all the economic theories that are related to it.

I think that we feel a little bit more comfortable today than we did when Wesley Mitchell started when we contemplated the business cycle as an almost "natural phenomenon." That didn't take much more than support of one of the great foundations to keep it going and the genius, conviction, and leadership of a Wesley Mitchell and the people associated with him. That national bureau has people from the universities around the country associated with it, students and so on, and over time that ripple has been enlarged.

Mr. DAVIS. Then your answer is that if even one able person, if he had the conviction and the dedication, might produce substantial results. But if it were a matter that involved a substantial outlay of money, then, of course, you would have to have a broader base of acceptance. It might even become a political question.

In that connection, do you feel there is a pressing need now for added effort in the social science field?

Dr. HERRING. I do.

Mr. DAVIS. Is it broad enough to warrant substantial public funds?

Dr. HERRING. I think that it calls for public funds. As I said earlier, we already have public funds. It calls for organizational arrangements that will optimize the use of these funds. It calls for steady support over a span of time. It calls for strengthening within our universities predominantly I would say institutes or departments

where they do have a clear sense of direction in the leadership and a basis that can be built upon.

For example, I can think, without being too particular, I can think of the plight of the man heading an important research institute in any 1 of 50 universities today. He has to meet a payroll. He is on term grants. The common picture has been that he spends probably, what, a third of his time trying to anticipate how he is going to meet the payroll over the next period. That isn't any way to run a university research operation; it is wasteful of time and talent.

I just returned from a few days at one of our leading institutions in the West reviewing the research experience in that institution over the last 10 years or so. I would prefer not to identify it, and just use it as a basis for illustration. One problem there was to get enough attention and support from the leadership of the university for these fields. What happened in this particular institution was that a group of social scientists ultimately won those top positions and their departments are doing quite nicely. So that is one factor: who sits in the decisionmaking position has great influence with respect to a variety of fields. Another element in the picture was that they had to provide research conditions that would attract to that institution really top people, and to do that you have to have support for their research, and they have to have students around who are alert and interested and very able. When you get such conditions then you can begin to build one of these research situations where you can expect accelerated consequences. Well, I think, Congressman Davis, that there are indications that over the next decade because it takes time to do these things, the chances of building have never been better, the problems have never been so demanding, and we do have now, what shall I say, a nucleus.

But, Mr. Chairman, one point that should be emphasized in responding to Congressman Davis' question is the sheer phenomenon of numbers. For example, if you take all the social scientists in our social science societies and add them up, you have a figure that about equals the number of chemists in the country. In other words, there is a problem of building more careers, attracting more people to the social sciences. This pinch of numbers is felt not only nationally in dealing with the matters I have just been talking about, but also internationally when we try to respond to requests from other countries for specialists. I have recently been concerned with a review of the Fulbright program, where our council is concerned with the other research councils in the administration of grants to advanced personnel in service overseas, and the requests from other countries for specialists in these fields just can't be met.

Mr. Davis. I have one other comment. Once you leave the field of the natural or physical sciences and move over into the social sciences you have of necessity moved from a field of complete nonpartisanship where you are dealing let's say with solid-state physics to a field which of necessity involves interpersonal relationships. It seems to me before a very big effort could be mounted in the social sciences, of course, as we pointed out earlier, it would become a political question and such studies are far more politically vulnerable by people who are not especially sold on intellectual pursuits. Anyhow, it might

make success far harder to come by in the field of sociology than it would in the other sciences.

Dr. HERRING. I think that is probably so. That isn't to say that the social and political consequences of public policy that are derived from, well, take the most spectacular example, the atom bomb, don't create very real political differences among scientists and between scientists and the public. I might say parenthetically that I served as the secretary for the Atomic Energy Commission of the United Nations in 1946, and sitting there with the group trying to do something about this brought home to me very much the enormous impact of science.

Mr. DAVIS. That bomb became a sociological problem.

Dr. HERRING. That is right, and a political problem of the first order. Can you think of a bigger political problem in the world today? I can't.

Mr. DAVIS. I certainly cannot.

Dr. HERRING. And when you take the varied responses of the great scientists of the country to that question, you find that we are all human, we all have our opinions about things. One could go on with that, but it seems to me that the main point is that these social science disciplines are by their very nature, by using that word "discipline," they are efforts, they are endeavors to be analytical. And while they at times fail, the important thing is that these are deliberate rational efforts of men trying to think analytically about problems which as you say by their very nature are at times highly controversial.

Mr. DAVIS. Thank you.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Dr. Herring, in interrogating representatives from the National Science Foundation we were informed that the relative percentage of proposals funded in the social sciences is approximately the same as those funded in the physical sciences; however, the overall percentage level is probably in the neighborhood of about 5 percent. But it leaves me at a loss to understand why we aren't funding more social science basic research through the National Science Foundation. Can you offer an explanation as to why we have such a low level of support? Is it possible that these proposals may be rather large numerically, but the amount of funds required are relatively low?

What is the answer to this situation which seems to make it appear that the National Science Foundation is being equally fair to the social sciences as to the physical and health sciences?

Dr. HERRING. Well, Congressman Brown, I will offer my opinions on this. I think the question might perhaps be answered in better factual terms by those who are directly concerned with it. It would be my impression that you find in the proposals that are presented to the Foundation certain assumptions, shall we say, as to what would be more or less likely to receive a favorable response. In other words, the public impression of what the NSF policy is would be in some degree reflected in the requests that are made. As a clear impression is gained of the scope of the Foundation's program and of the receptivity of the staff there to a broadening conception, I think that situation will improve. I think you will agree in the light of the background that I have been sketching it is not too surprising that there may be certain preconceptions about what is worthwhile submitting, and these preconceptions may not be entirely accurate.

Mr. BROWN. Yes, I think this is true. As long as the National Science Foundation takes the position that it is looking at the whole broad gamut of basic research and science research and is funding a relatively equal proportion all across the line, it is more or less immune to criticism. Perhaps the criticism should be directed to the social scientists themselves for not proposing a larger number of projects which can be funded. Perhaps they should overlook the fact that admittedly the basic role of the Foundation was in the physical science to begin with but that their mandate is broad enough to cover the social sciences. Perhaps if the NSF received a large number of social science proposals that were sound and were put in the position of either having to fund them or turn them down, then this would bring the problem to a head.

Dr. HERRING. I think that is right. I have this observation to offer. The fact that the agency is predominantly concerned with the natural sciences means that very often those in charge of the social sciences have to think: "Now, what would be an equivalent?" You start off in the language, let's say, of physics, and try to find some counterpart to that in the field of sociology. Well, there again you see it is sort of twisting things to meet a pattern, and it does make for difficulties. If you take the actual figures that I have here before me, for 1965, the grants activated came to $10,279,000, that is to say the funds that were approved.

The funds requested of the division came to $34 million, and the funds granted were just over $10 million. So it is about that proportion. I think that your question brings out the point I was trying to emphasize, and I am grateful to you for it, because I don't think, Congressman Brown, it is enough to sit back and say, well, we haven't had the proposals we want, because it isn't simply a matter of writing out a proposal and dropping it in the mail; it is a much more complex thing. It goes back to the points I was making about having the situation within the university where they can formulate a grant and carry through an ambitious program if they get the money. And there again it comes to this point of personnel.

Mr. DADDARIO. Will the gentleman yield?

Mr. BROWN. Yes.

Mr. DADDARIO. You are reemphasizing, in answer to Mr. Brown's point, the ideas you stressed in regard to developmental support, continuity, and programing of this support within an agency that does not necessarily have assigned to it a mission objective?

Dr. HERRING. Yes.

Mr. DADDARIO. Does that fit properly?

Dr. HERRING. Yes.

Mr. DADDARIO. Thank you, Mr. Brown.

Mr. BROWN. I would like to go back to your original anecdote about your conversation with the French gentleman about what we could offer to Africa. The Frenchman indicated that they could offer French, which I presume means French culture as represented by the language and all those things that go into it, and that the United States can offer the social sciences. I presume you would agree that as far as Africa is concerned there isn't a great deal that we can offer in the basic sciences because in today's environment high energy accelerators or the technology of atom bombs aren't too appropriate in

Africa. The question of what we can offer in the social sciences is an intriguing one because I think this is probably what you were getting at. What they need in Africa is an understanding of public administration, of economic organization, and of social relationships of which we have a true science in the United States. What is offered by the cold war bloc, the Communist bloc, is dogma. If there is any real strength in the competition between the two systems, it would be our contribution of science to the problems that they have in these areas as contrasted to dogma which comes from the other bloc. Am I correct in this analysis?

Dr. HERRING. That would be my opinion, Congressman Brown.

Mr. BROWN. Do you feel that if this were presented in little more vigorous terms to the policymakers of this country that they could begin to see an equal relevance to social science that they attach now to physical science in the competition with the Communist bloc?

Dr. HERRING. Well, I think there is a much wider interest and appreciation of these fields now than there has been because of some of the considerations which you have named. As you were talking I was thinking of a long trip I had in Nigeria. I went there with the intent of trying to get a better impression of what the Nigerians were going to do in implementing the Ashby report. Sir Eric Ashby and an international committee had studied the educational needs of Nigeria and had come up with recommendations. I had the opportunity of trying to find out what they were going to do about it. The situation sort of reminded me of home in a way. They wanted more education, they wanted it fast, and there were a good many political overtones to the requests geographically viewed for support for education. But the point of my mentioning it here is to emphasize in dealing with these developing countries you are truly dealing with underdeveloped, and the problem of how to begin and how to come to grips with something when it is there in such an underdeveloped state is really compelling when you come right up against it. So, even with the best will in the world to get the social sciences to work in such a country requires some kind of infrastructure on their part, enough of a bureaucracy to deal with it, enough political stability to make a decision that will stick, and so on, so that while I agree that we have a good deal that we could offer if we had the people who were ready to go over there and do it in greater measure, you do truly deal with a very underdeveloped set of institutions.

Mr. BROWN. I am not so much concerned with the mechanics, which I realize are complicated, because the mechanics are really applied research. I am talking about basic social science research to understand the problem that exists here, and then to be able to transmit that problem through applied social science research to the solution of problems that face these areas. This would be, I presume, a part of these area studies. In your opinion, are we devoting sufficient resources to support of these various studies that you have mentioned, not considering whether they are basic science or applied science, but, in general, are we supporting the matter?

Dr. HERRING. In general over the long pull we have got to do much more than we are doing because of the dimension of the problem. For our own sakes we need a clear national understanding, of what our international relationships are and how we could better implement

some of our policy commitments, but, of course, there is also the need of helping to bring these other countries up to a state where we could more effectively communicate and understand each other.

Mr. BROWN. You have avoided making a direct response to the question of whether or not the National Science Foundation is the proper body for providing the increased support which you obviously feel is necessary for basic research in the social sciences. You pointed out the emphasis given in Britain to this support and the alternative mechanisms that could be offered. Do you have a recommendation as how through modification of the National Science Foundation or through allocation of this responsibility to another organization that we could adequately meet this problem?

Dr. HERRING. Well, as you can see, I am hesitant to come in with quick answers on a problem of that sort. I think, as I said earlier, that the readiness to broaden the approach, to be somewhat more inclusive, to emphasize the broader rather than the narrower approach, that attitude commends itself to me on the part of the National Science Foundation, and I think that in terms of, if you say, immediate next steps, I would say that would be a good thing.

With respect to the other problem of how best to find a voice, I think it is of sufficient complexity to warrant inviting a number of people who are well informed to think about it. I could sound off with some judgment here this morning, but I would rather not. I think it is a problem of enough depth and complexity to warrant some more fact gathering, some more discussion, to see what others who are close to it may feel may be the sound approach.

Mr. BROWN. I have no further questions, Mr. Chairman.

Mr. DADDARIO. Mr. Vivian?

Mr. VIVIAN. None.

Mr. DAVIS. Dr. Herring, there is one question that occurred to me during the questions by Mr. Brown, and that is this. I think underlying all of our science effort is the idea that there is human benefit to be gained.

Of course, if you are going to use the phrase basic science you eliminate that particular goal as being in mind because you are saying to yourself all I am trying to do is push back the frontiers of knowledge in this field. Now, awhile ago you said that you perceived that it was going to be difficult to find a way to get things accepted in Nigeria with the state of the culture that you found there. Actually, weren't you talking about social therapy as distinguished from science?

Dr. HERRING. Well, let me see if I can be precise as to what I was thinking about.

Here is a vivid experience that comes to mind that is I think germane to your question. I spent sometime at the university in Ibadan, and I visited the hospital of the medical school, a very modern hospital, and I went into the ward, and the young physician in charge said, "See those patients, most of them are in a bed for the first time in their lives. They are very well behaved. Hundreds of people come here every morning, and since we are a medical college hospital, we send one of the interns out with some aspirin and he distributes pills and then he selects, say, the hundred people that we can handle, and we need for our medical instruction purposes." I think that that

sort of epitomizes the basic question you are asking. There they couldn't be ameliorative, you see, because the problem is too enormous. Their long-range effort at dealing with the problem is to try to train enough physicians. In other words, they have to take a developmental teaching approach to the problem of medicine there because they can't handle it with the resources they have. I said to this man, well, "Why don't you train some therapists or medical aids who could do a little something by way of amelioration?"

He said, "We don't want to have a new kind of medicine man around. We don't want to break away from the standards of scientific medicine."

Well, it lingers in my mind as a rather vivid illustration of the dilemma that confronts the person who is concerned with a choice between, A, trying to apply therapy however inadequately in view of the dimensions of the need, and, B, trying to build more basically so that in the longer run, as in this instance, there would be doctors to deal with the problem and scientific medicine established.

Mr. DAVIS. You also talked about the Frenchman offering French to the Africans, and he said that the Americans could offer sociology. Was he talking about practicing sociology on the Africans or teaching the Africans the science of sociology?

Dr. HERRING. I don't know. It was one of these passing episodes. If you want me to try to interpret what sense there was in his comment, I would say that in a very profound way—and he was a very cultivated, sophisticated Frenchman—he was saying that we have this conception of French culture, with all of its style, its subtlety, its tradition, its elan, and you folks, you see, you have your more down to earth kind of factual way of trying to analyze things and you don't have the style and the excitement that you get from studying French literature, let's say, and coming to Paris to pursue it, but you do have a way of dealing with practical problems. I think that is what he was trying to say. In other words, it seems to me he was saying as you look at the Sorbonne you see one thing, as you look at the Universities of Iowa or Kansas or Alabama or Georgia or Texas you see institutions that have a way of getting into the problems of the people and working with them. That is what I got out of it.

Mr. DAVIS. I thank you. That is all.

Mr. DADDARIO. Dr. Herring, we have had you as a witness a little longer than I had intended, but I did want to let all the members have an opportunity to participate. Thank you for coming. I hope we might be able to send some additional questions to you.[1] There are a whole series of questions which have come to mind during the course of this morning's activity, and I am sure that certain members of the staff will also offer some suggestions. It has been a very interesting and helpful participation.

Dr. HERRING. Mr. Chairman, I have enjoyed it very much, and I thank you for this opportunity. If I can be helpful in any way, please call upon me.

Mr. DADDARIO. Our next witness is Mr. Herman Pollack, the Acting Director of the International Scientific and Technological Affairs of the State Department. We are pleased to have you, Mr. Pollack. My apologies for keeping you so long.

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

STATEMENT OF HERMAN POLLACK, ACTING DIRECTOR, INTERNATIONAL SCIENTIFIC AND TECHNOLOGICAL AFFAIRS; ACCOMPANIED BY DR. WALLACE JOYCE, DIRECTOR, GENERAL SCIENCE AFFAIRS; AND ROBERT F. PACKARD, DIRECTOR, OUTER SPACE AFFAIRS

Mr. POLLACK. I always welcome an opportunity to hear Dr. Herring.

Mr. DADDARIO. We are anxious to hear your statement.

Mr. POLLACK. My intention is to skim over and highlight the early part of my statement and spend a bit more time on the latter part.

(Mr. Pollack's prepared statement appears after his opening remarks.)

Mr. POLLACK. In my statement I point out that unlike most of the witnesses testifying in these hearings, I am not a scientist. I have spent 19 years with the Department of State, largely devoted to administration of the Department and the substance of foreign affairs. I call this to your attention early because I think it will illuminate the perspective with which I view the subject at hand. The statement outlines the underpinning and the characteristics of science that give rise to the interaction of science with foreign affairs. It also describes briefly the Department's organizational response to that interaction over the past 15 years. It describes the history and organization of the office with which I am associated. It points out that the function of International Scientific and Technological Affairs, I will refer to that hereafter as SCI, is to insure that the full potential of the opportunities afforded by modern science for the benefit of our foreign policy and relations is recognized and utilized by the Department. Our success in doing that is going to be determined in part by the understanding that can be created throughout the Department as to what these opportunities are. It is also going to be determined in part by the way in which the Government agencies responsible for science here are able to organize their participation in the approach to these opportunities. There are inhibitions which I think exist which I will come back to later.

I think, too, I should have pointed out or highlighted to a greater extent than I do, that one of our functions and a major function is to anticipate the kinds of political and international problems that will be posed by scientific and technological developments in a hope that we might anticipate, we might make preparations that would enable the United States and other governments concerned to deal with these problems in a more rational and sensible fashion than we otherwise would. Thus, it is probably time that we began thinking, indeed we already are, but thinking perhaps more strenuously than we now are, as to what the implications may be of current progress in the atmospheric sciences, the lack of respect for boundaries, inherent in efforts to modify weather, and the significance of this. The statement goes on to describe the involvement of the National Science Foundation in international activities and points out that the National Science Foundation does its work in the international field exceedingly well. I am now picking up, sir, on page 10. I am happy to say that the relations between the NSF and Department of State on

all of these activities are intimate and harmonious. The fact that such Foundation interests outside the United States are devoted essentially to the substance of science while the Department's concern rests with its significance abroad to our foreign policy and relations and with its implications for our position in world affairs has helped to define jurisdictions satisfactorily up to now.

As I have indicated earlier, the Department's appreciation of science's interaction with foreign policy is maturing rapidly. So, I think, is the perception of the scientist and the scientific community on the same subject. This gives rise to consideration of the future and the question of whether NSF's international role should be enlarged.

I now approach that possible inhibition that I mentioned earlier. My approach is as follows:

The nature of the world we live in is such that the successful conduct of our foreign relations and the attainment of the objectives of our foreign policy require the effective utilization of a great variety of resources. This has led in the very recent past to major international programs in the fields of information, economic assistance, and cultural exchanges.

What is it that the United States is attempting to do in utilizing these resources for foreign policy purposes? Put most simply, it is to create a broadly based working partnership of free countries engaged in mutual tasks which serve common interests and compatible objectives. In this process we must put forward our best efforts and our best resources. I submit that among these are our capability and attainments in science and technology. Yet it seems to me that we may perhaps have been hesitant to so utilize American science because of the apprehension on the part of some, perhaps many, that to use science in this way would be to identify it with political purposes and in the process destroy some of the very integrity of science itself.

This is by no means necessarily so. And it will not be so if use of science for foreign policy purposes is wisely conceived and wisely administered. As long as the scientific relationship is in of itself scientifically valuable and as long as it is administered under criteria customary to such relationships, I submit that the integrity of science is not affected. Wherever these conditions are not met, the political purpose will in fact not be attained. Although the analogy may be a poor one, it is as if we send abroad under our cultural program a second-rate artistic performer. We would get a poor press and fail to achieve the objectives sought.

Thus I am brought to the conclusion that the interests of good international science and good foreign policy are not contradictory. If for any reason they should be, then neither the scientific goal nor the policy objective is likely to be attained. It seems clear that there will be increasing opportunities in which the course of wisdom will dictate an effort to utilize scientific cooperation and scientific relationships specifically for the purposes of improving our foreign relations and for attaining objectives of foreign policy. Rather than shy away from such opportunities, it might be better to examine whether we are sufficiently well equipped to seek and to exploit them.

The effective development of such initiatives requires in the first instance that we overcome our reluctance to take them. Beyond that many things are required, including the development of greater scientific literacy on the part of the foreign policy practitioner and simultaneously greater foreign affairs literacy on the part of the scientific administrator and planner.

The implementation of programs developed as a consequence of such initiatives leads us directly to the matter of NSF's role. We have a highly organized Government and the rules under which it is managed require each department and agency to observe rather carefully the boundaries set for it. These rules are enforced by both the Congress and the executive branch. Science however is no more restricted by bureaucratic boundaries than it is by national boundaries. It may be anticipated that we will encounter frequently in the future proposals for international scientific activity or cooperation that do not readily match a bureaucratic base in our governmental structure—that involve responsibilities of two or more agencies. In situations such as this it might be desirable for the Department of State to be able to turn to an organization such as the National Science Foundation whose perspective is Government-wide for assistance, initially at least, in the conduct or coordination of the scientific content of the program.

We need also to be aware of the inhibitions to creative initiatives imposed by the hard fact that typically a domestic agency has no authority to expend funds for scientific activities designed to serve an international purpose. Domestic agencies justify their budgets in terms of domestic benefits. This pertains, in large measure, to the NSF itself.

These considerations suggest that it is timely to think again how the U.S. Government should organize itself for the effective use of its scientific resources in support of its foreign policy and what kind of legislative mandate and authority should be provided. Of possible relevance is Public Law 86–610, dated July 12, 1960, which provides, in part, authority to engage in cooperative endeavors in health research and related activities (1) to advance the status of the health sciences in the United States and (2) to advance the international status of the health sciences. Perhaps comparable authority to advance the international status of science per se should be specifically granted to the President or to an executive agency such as the National Science Foundation.

The essential point is that the effective and legitimate employment of our tremendous science resources in support of foreign policy objectives would benefit from the availability and utilization of such authority.

Dr. Haworth and I will be considering this need and related matters further in the course of the discussions we now have underway on the common interests of the National Science Foundation and the Department of State.

That concludes my formal remarks, Mr. Chairman. I will be pleased to answer any questions.

PREPARED STATEMENT OF MR. HERMAN POLLACK, ACTING DIRECTOR, INTERNATIONAL SCIENTIFIC AND TECHNOLOGICAL AFFAIRS

Mr. Chairman and members of the subcommittee, my name is Herman Pollack. Since January 1 of this year I have been Acting Director of International Scientific and Technological Affairs in the Department of State. My permanent assignment in my organization is that of Deputy Director. Unlike most of the witnesses testifying in these hearings, I am not a scientist. The 19 years I have been with the Department of State have been devoted to the administration of the Department and the substance of foreign affairs. I offer these personal remarks at the outset, since my background undoubtedly affects the perspective with which I view the subject we are discussing.

I am pleased to have been invited by this committee to participate in this comprehensive review of the National Science Foundation. Because the Department's relations with NSF are bound up with the relationship between science and foreign affairs, I shall direct my remarks first to the considerations of U.S. involvement in international science; then, I shall refer to the Department's role in this field as it relates to NSF's foreign activities, and finally I shall consider certain aspects of the future expanding international role of science to foreign policy and the possible implications of this to the role of NSF.

It has become almost a commonplace to regard science and the successful pursuit of technology as a new important dimension in the conduct of foreign affairs. The question of how and why this is so is a very proper subject of this inquiry. From the viewpoint of the Department of State first-rate science per se generates opportunities in foreign affairs. I shall return to this theme later.

In detailing the projection of U.S. science abroad two sets of considerations are involved. The scientific considerations include the following:

Science is a unity. Its limits are the universe and the capability of the human mind. Its possession of unity, universality, and independence makes it truly supranational in character. This inherent cohesive force can be facilitated or retarded by national policies, attitudes, and mechanisms. It is wise public policy to encourage and support extensive international relationships for scientists and for scientific institutions.

Scientific excellence is dispersed. It is not an exclusive national possession. Scientists' talents and capabilities and the quality of their institutions in many lands constitute a valuable resource with which we must be associated.

The geography of phenomena is global. Major areas of scientific inquiry, such as oceanography, geophysics, meteorology, and astrophysics, can be approached in meaningful form only on a global basis. A framework of international relationships is therefore essential to scientific interest and development in those areas of study.

Given the intimate connection between the advancement of science and our national welfare, the above considerations would seem to be compelling for engaging the United States in international scientific undertakings. But there are additional considerations:

Science advances U.S. foreign policy. Scientific enterprises present exceptional opportunities to enhance the prestige, leadership, and influence of the United States. They provide a means of cooperation based upon people's interest in the advancement of knowledge and in its application for the common good. They are perhaps the least controversial and therefore potentially among the most useful ties not only with the less-developed world but also with our allies, the Soviet Union, and other members of the Communist bloc.

The language of science is worldwide. Its independent intellectual expression correlates with our philosophy of free speech and free inquiry. In the long run it reduces the tyrannical control of man's mind even in the most rigid dictatorship. Lysenko's genetics illustrates the essential incompatibility of science and dictatorship.

Science is essential to strengthen the security of the United States and the free world. Capability in science and technology is a necessary base of national and military strength. International activity in this area, especially with our allies, is required in the interests of common defense and world peace.

International relationships enhance domestic programs in technical areas. National developments in technology require close relationships with related professional endeavor elsewhere in the world. Important facets of this are sup-

port of research and training abroad, particularly by and for Americans, participation in international organizations and other collaborative ventures. The products of foreign science can favorably influence the quality and productivity of our own.

I might note that every relationship abroad, including those involving science, has political content and the Department is concerned therefore. It is relevant briefly to describe the Department of State's response to the increasing impact of science upon foreign relations before treating more specifically of the interrelationship of Department and Foundation responsibilities.

Despite Benjamin Franklin's amalgamation of science and politics in his own person, the Department's professional awareness of science as an important factor in the conduct of foreign affairs has developed only recently—in parallel with the 15-year span of the NSF. Whereas the First World War brought science into general contact with governmental policy, it took World War II and its aftermath to make scientific counsel and indispensable function of foreign policy.

The Office of the Science Adviser in the Department was first created in 1951. It brought science as a facet of foreign affairs into better focus and resulted in the appointment of scientific attachés to London, Paris, Stockholm, and Tokyo. What has since become an area of the Department designated as International Scientific and Technological Affairs is currently responsible for 23 scientific and assistant scientific attachés posted to 16 major world capitals.

The attaché's principal function is to provide advice and assistance to the Ambassador in the management of problems which have significant scientific or technological content or which would be illuminated by inputs from the perspective of a scientist or engineer. The attaché keeps the Department and the U.S. Government abreast of developments in the local organization of science and technology and in governmental policy and planning for scientific research and development. The overall subject is intricate, calling for a scientist's understanding combined with a knowledge of the local scene and a feel for policy. Also typically within the purview of his office are cooperation in space matters, in the Antarctic, in scientific information, and in proposals for mutual effort in the field of public health. Other subjects for his attention are national attitudes toward OECD, NATO, and UNESCO science and their relation to U.S. views of those agencies' scientific activities. These matters and many more of scientific content represent a not inconsiderable part of the embassy's concerns. They underline, too, the point that the scientific attaché's offices are of necessity an integral part of U.S. Embassy diplomatic operations.

The assessments regarding the local science scene provided by the attaché make an important contribution to the Department's ability to formulate overall policy. For example, special insights into a nation's future position in the economic and political spectrum may be offered by analysis of its provision for student training in engineering and scientific disciplines and its investment in industrial oriented research and similar factors.

Domestically our office, familiarly known as SCI, is organized into three units. Two of these perform respectively the important functions of promoting U.S. interests in atomic energy and in space matters where they go international. The multiplying interests and repercussions abroad of other sciences are the responsibility of SCI's General Science Unit, which administers in addition the scientific attaché program.

The perception of SCI's role by the Department of State has been evolving for the past 15 years. It is evolving at this time. It is my impression that the development of this role and of the Department's understanding of the science-foreign affairs interaction is maturing rapidly. Basically, it is SCI's function to insure that the full potential of the opportunities afforded by modern science for the benefit of our foreign policy and relations is recognized and utilized by the Department, and in turn to insure that our international affairs are so conducted as to facilitate the international pursuit of scientific objectives. As does the attaché to his ambassador, SCI attempts to provide the Secretary and other principal officers with advice on the political and policy implications of subjects having technical content. We earn our bread and butter by the work we do in negotiating international agreements for scientific cooperation and in planning for and facilitating international scientific activities and programs.

SCI's Director is Chairman of the International Committee of the Federal Council for Science and Technology, the Committee on Foreign Desalting Programs and the newly formed Interagency Arctic Working Group. The Department is represented by SCI on more than a dozen interagency committees concerned with scientific subjects.

The Department's recognition of the need for greater and wider spread competence in the interaction of science and foreign affairs had led to the establishment of a science, technology and foreign affairs course last year which is now a permanent part of the curriculum at the Foreign Service Institute. Within the past few months we have identified at every embassy where a scientific attaché is not assigned a capable officer who will be specifically responsible for following the scientific scene and reporting on significant developments. There is currently under consideration a proposal for an officer exchange program in the politico-scientific field, somewhat comparable to the one now in successful operation with the Department of Defense in the politico-military field. Consideration is also being given to ways to attract more science-trained personnel to the Foreign Service examinations.

The involvement of the National Science Foundation in activities with a foreign or international component is usually justified in terms of the pursuit of its mission to advance science in the United States. Some of its programs without explicit design for foreign or international involvement include normal support programs in certain disciplines characterized by a high movement of research investigators across national boundaries as in anthropology and oceanography. A small but important number of research grants is made each year to foreign investigators, usually justified by the contribution to be made by them complementarily with U.S. efforts. The Department examines and approves these grants to assure that the action supported does not contradict foreign policy.

NSF likewise provides support for the improved collection and dissemination of scientific information. A part of that effort is understandably aimed at foreign performers—the Abstracting Board of the International Council of Scientific Unions (ICSU), The International Federation of Documentation, the British Association of Special Libraries and Information Bureaus, etc. An obvious avenue of information exchange is that of people. By its fellowship programs and travel grants the Foundation enables several hundred American scientists each year to make foreign contacts and several scores of foreign scientists to attend U.S. scientific meetings.

An obvious projection of all such activities is the large, often global experiment or concerted synoptic study in which U.S. scientists participate with their foreign colleagues; to that end the Foundation budgets for and coordinates, on behalf of the U.S. Government, programs such as the International Year of the Quiet Sun and the International Indian Ocean Expedition.

In a somewhat different category are those activities undertaken by the Foundation at the request or instigation of other entities concerned with international science including the Department of State. On behalf of several agencies it administers a program for the translation of Soviet and Eastern European scientific periodicals and books, employing for the purpose U.S.-owned excess foreign currencies. On behalf of the Agency for International Development (and using AID funds) it operates in Central and South America two programs in science education. And at the request of the Department of State it funds and administers the United States-Japan cooperative science program; coordinates and largely funds interagency projects under the 12-nation Antarctic Treaty program; administers the U.S. portion of the North Atlantic Treaty Organization (NATO) fellowships program; and provides important backstopping functions with respect to the OECD science program—arranging for appropriate substantive U.S. participation in the several programs' elements.

This partial list indicates the scope and variety of the Foundation's overseas activities. It performs these tasks exceedingly well. Its perspective is pleasingly broad and nonbureaucratic. I am happy to say that the relations between the NSF and Department of State on all of these activities are intimate and harmonious. The fact that such Foundation interests outside the United States are devoted essentially to the substance of science while the Department's con-

cern rests with its significance abroad to our foreign policy and relations and with its implications for our position in world affairs has helped to define jurisdictions satisfactorily up to now.

As I have indicated earlier, the Department's appreciation of science's interaction with foreign policy is maturing rapidly. So I think is the perception of the scientist and the scientific community on the same subject. This gives rise to consideration of the future and the question of whether NSF's international role should be enlarged. My approach to this question is as follows:

The nature of the world we live in is such that the successful conduct of our foreign relations and the attainment of the objectives of our foreign policy require the effective utilization of a great variety of resources. This has led, in the very recent past, to major international programs in the fields of information, economic assistance, and cultural exchanges. What is it that the United States is attempting to do in utilizing these resources for foreign policy purposes? Put most simply, it is to create a broadly based working partnership of free countries engaged in mutual tasks which serve common interests and compatible objectives. In this process, we must put forward our best efforts and our best resources. I submit that among these are our capability and attainments in science and technology. Yet it seems to me that we may, perhaps, have been hesitant to so utilize American science because of the apprehension on the part of some, perhaps many, that to use science in this way would be to identify it with political purposes and in the process destroy some of the very integrity of science itself.

This is by no means necessarily so. And it will not be so if use of science for foreign policy purposes is wisely conceived and wisely administered. As long as the scientific relationship is in of itself scientifically valuable and as long as it is administered under criteria customary to such relationships, I submit that the integrity of science is not affected. Wherever these conditions are not met, the political purpose will in fact not be attained. Although the analogy may be a poor one, it is as if we sent abroad, under our cultural program, a second-rate artistic performer. We would get a poor press and fail to achieve the objectives sought.

Thus I am brought to the conclusion that the interests of good international science and good foreign policy are not contradictory. If for any reason they should be, then neither the scientific goal nor the policy objective is likely to be attained. It seems clear that there will be increasing opportunities in which the course of wisdom will dictate an effort to utilize scientific cooperation and scientific relationships specifically for the purposes of improving our foreign relations and for attaining objectives of foreign policy. Rather than shy away from such opportunities, it might be better to examine whether we are sufficiently well equipped to seek and to exploit them.

The effective development of such initiatives requires, in the first instance, that we overcome our reluctance to take them. Beyond that many things are required, including the development of greater scientific literacy on the part of the foreign policy practitioner and simultaneously greater foreign affairs literacy on the part of the scientific administrator and planner.

The implementation of programs developed as a consequence of such initiatives leads us directly to the matter of the National Science Foundation's role. We have a highly organized Government and the rules under which it is managed require each department and agency to observe rather carefully the boundaries set for it. These rules are enforced by both the Congress and the executive branch. Science, however, is no more restricted by bureaucratic boundaries than it is by national boundaries. It may be anticipated that we will encounter frequently, in the future, proposals for international scientific activity or cooperation that do not readily match a bureaucratic base in our governmental structure—that involve responsibilities of two or more agencies. In situations such as this it might be desirable for the Department of State to be able to turn to an organization such as the National Science Foundation whose perspective is Government-wide for assistance, initially at least, in the conduct or coordination of the scientific content of the program.

We need, also, to be aware of the inhibitions to creative initiatives imposed by the hard fact that typically a domestic agency has no authority to expend funds for scientific activities designed to serve an international purpose. Domestic agencies justify their budgets in terms of domestic benefits. This pertains, in large measure, to the National Science Foundation itself.

These considerations suggest that it is timely to think again how the U.S. Government should organize itself for the effective use of its scientific resources in support of its foreign policy and what kind of legislative mandate and authority should be provided. Of possible relevance is Public Law 86-610 dated July 12, 1960, which provides, in part, authority to engage in cooperative endeavors in health research and related activities (1) to advance the status of the health sciences in the United States, and (2) to advance the international status of the health sciences. Perhaps comparable authority to advance the international status of science per se should be specifically granted to the President or to an executive agency such as the National Science Foundation.

The essential point is that the effective and legitimate employment of our tremendous science resources in support of foreign policy objectives would benefit from the availability and utilization of such authority. Dr. Haworth and I will be considering this need and related matters further in the course of the discussions we now have underway on the common interests of the National Science Foundation and the Department of State.

Mr. Daddario. Thank you. Mr. Vivian?

Mr. Vivian. You comment that inhibitions to create initiatives are imposed by the fact that a domestic agency has no authority to expend funds for scientific activities designed to serve an international purpose. I presume, however, that the State Department does have such control or there is no such limitations on its authority. I would like to get some idea of the scope of funds you transfer to the National Science Foundation for the purpose of stimulating peaceful scientific activities abroad. I am not interested in any funds used for other purposes.

Mr. Pollack. We transfer no funds to the National Science Foundation. There is on specific authority available to the Department of State for this purpose. I think the only amount of money that we transfer for a scientific purpose would be a small grant that we make annually to the National Academy of Sciences to purchase, as it were, en mass consultation and advice from the National Academy of Sciences on some of our international scientific programs. That is in the amount of $25,000 per year.

Mr. Vivian. I plan to come back to that momentarily. Is National Science Foundation's budget request for international activities reviewed by the State Department? How do you effect cooperation between the National Science Foundation and the State Department in the context of the National Science Foundation budget?

Mr. Pollack. I am not familiar with the way in which the National Science Foundation puts its budget together. I do not believe that their budget contains a section devoted to international activities per se, but they do consult with us on the scope and size of the Antarctic program, they, of course, are acting at our request with respect to the United States-Japan scientific cooperation program, and there would be consultation throughout on all of the international activities which I have mentioned in my statement.

Mr. Vivian. There is, however, no review, nation by nation, of the extent to which the State Department desires to have scientific activities supported by this Nation or by UNESCO or a similar organization, and the extent to which the National Science Foundation should play a role in this subject?

Mr. POLLACK. Not at this time, sir.

Mr. VIVIAN. Would you regard such a step as desirable or not?

Mr. POLLACK. I think at some point in time it would be desirable. I don't think the Department of State, at this point, nor the Foundation, either, is equipped to do this function usefully.

Mr. VIVIAN. Is there any other organization which is equipped to do so?

Mr. POLLACK. No, sir.

Mr. VIVIAN. When do you think it should have been done?

Mr. POLLACK. Several years ago.

Mr. VIVIAN. What has happened under the authority of Public Law 86–610?

Mr. POLLACK. That authority, the second part of it, which was the authority to promote the international status of the health sciences, was authority granted to the President. He has, as I understand it, not yet made a delegation. There have only been two specific instances in which he has employed this authority, and both of them involved specific action on his part. One was a program relating to a Latin American program—I think a grant to the OAS—and I can't recall at this point what the second was.

Mr. VIVIAN. In other words, whatever the benefits which Public Law 86–610 is intended to provide or the wisdom of its passage, it has not as yet had much effect on the international science?

Mr. POLLACK. That is right. The current employment of this authority is under consideration with respect to the new program that not as yet had much effect on the international scene?

Mr. VIVIAN. It does not, however, convey any authority except in the health sciences?

Mr. POLLACK. No, sir.

Mr. VIVIAN. Let me switch to a related question. You say on page 8:

> A small but important number of research grants are made each year to foreign investigators, usually justified by the contribution to be made by them complementarily with U.S. efforts.

These are NSF grants, presumably, to which you are referring.

Mr. POLLACK. Yes, sir.

Mr. VIVIAN. What total volume of funds is involved? Approximately.

Dr. JOYCE. I do not have a figure on the NSF part. We have just the military and other agencies.

Mr. VIVIAN. I was going to ask for those next.

Dr. JOYCE. Perhaps someone from NSF is here.

Mr. POLLACK. This is Wallace Joyce, who is Chief of the International Science Section in our office.

Mr. DADDARIO. Why don't you provide those for the record?

(The information requested is as follows:)

Federal obligations for basic research to foreign performers by region, country, and agency, fiscal year 1963

NOTE.—Definition of "foreign performers": A foreign performer is defined here as a government, citizen, or organization, either profit or nonprofit, conducting research and development, financed by the U.S. Government. A foreign performer within the concept of this definition is not a U.S. agency, citizen, or organization located abroad; also, funds reported do not include payments to foreign scientists working in the United States.

Dr. JOYCE. This report, Mr. Chairman, is provided by the National Science Foundation, and the information comes from the publication "Federal Funds for Research, Development, and Other Scientific Activities," volume 13. It is based on figures for fiscal year 1963, which is the last year for which firm material is on hand. Research and development, total abroad, $67.6 million, according to this chart, of which $19.1 million is placed by the Department of Defense, $48.5 million by other agencies, nondefense. It is broken down by regions. If you wish to have this, I can read them off.

Mr. VIVIAN. Could I ask that the information be provided in a tabulated or summary form? I would like to know what these other agencies are which utilized two or three times as much as the $19 million quoted.

Dr. JOYCE. We will have to develop that and provide it for the staff.

Mr. VIVIAN. I understand from your remarks on page 8 that there is a certain amount of money spent by NSF.

Mr. POLLACK. Yes.

Mr. VIVIAN. From my earlier questioning I gathered that the State Department played a very minor role in the amount of money NSF allocated for the purposes of these grants.

Mr. POLLACK. That is correct.

Mr. VIVIAN. In other words, the NSF gets this money from the Budget Bureau, and then you people, after they have it, help them spend it. Is that a fair statement?

Mr. POLLACK. It is not quite as bad as that. But the kind of guidance we are capable at this point of providing to the NSF doesn't amount to anything terribly firm on which to build up a budget program.

Mr. VIVIAN. I would like to complement the gentleman for his willingness to be self-critical for a moment. Not all agencies are quite prepared to do so.

Let me switch to another facet of the same subject. Wouldn't this data provide guidance as to the size of the contributions to overseas science by all the agencies who are expending funds overseas.

Dr. JOYCE. That is correct. This is research and development and also for basic research.

Mr. VIVIAN. That will include both facilities as well as operating funds?

Dr. JOYCE. I assume that it does, Mr. Vivian. I will have to check this, sir, with the NSF.

Mr. POLLACK. It does not include, I know, the NASA facilities for tracking.

Mr. VIVIAN. I am not concerned with that since it is for U.S. purposes even though located overseas.

On page 6 of your remarks you state:

> Special insights into the nation's future position in the economic and political spectrum may be offered by analysis of its provision for student training in engineering and scientific disciplines and its investment in industrial-oriented research and similar factors.

I would be quite fascinated to receive a report on what I will call the consequences of the insight which apparently have been gained. Are you in a position to make any brief remarks on the insight we gained into these specific questions as it pertains to the U.S.S.R., but more particularly to China?

Are you prepared to make any predictions as to the future position of China, for example, in the economic and political spectrum?

Mr. POLLACK. No. I am not, sir; not on China. That statement was put in here to reflect some information that was acquired with respect to national programs being pursued by Great Britain, France, Germany, and one or two other European countries. It gave some indication, as one factor among many, that would give some clues as to what the scene might look like in the 1970's in Europe if the current predictions were to stay firm.

Mr. VIVIAN. The 1970's aren't very far away.

Mr. POLLACK. That is right.

Mr. VIVIAN. I would like to go to some remarks made by Dr. Rabi, a very well know and very competent person. His prediction was that within 50 years China could be the top scientific nation in the world. Do any of your experiences in the State Department support such a contention?

Mr. POLLACK. No, sir. I am not aware of the fact that we currently have enough information on hand to indicate the current programs being pursued in China would have that consequence.

Mr. VIVIAN. Can we construe the Chinese atomic program as being a copy of the other programs elsewhere such as the Russian or the French?

Mr. POLLACK. I think a great deal of credit is to be given to the assistance they have obtained from the Soviet Union in their program.

Mr. VIVIAN. Did not the Soviet Union cut this off 6 or 8 years ago very drastically and very intentionally?

Mr. POLLACK. Yes.

Mr. VIVIAN. Then, have the Chinese progressed on their own since that time?

Mr. POLLACK. I am certain they have.

Mr. VIVIAN. I understand—and I am going entirely by unclassified literature——

Mr. POLLACK. That is all I am referring to.

Mr. VIVIAN (continuing). That the Chinese atomic bomb was of a fairly advanced type. Doesn't this suggest that their scientific progress may be fairly great?

Mr. POLLACK. It does, indeed, and I am not underestimating their scientific progress. What I am stating is that I am unaware of any basis now for making a rather firm quantitative prediction as to where they will stand 50 years hence.

Mr. VIVIAN. In the late 1940's the United States was convinced that Russia was a scientific ignoramus. I am very concerned that we as a nation are grossly underestimating the competence of China in the scientific field. I think Japan is a classical example of what can and has been accomplished by a nation with a very similar type of intellectual background. I think it is something for us to be interested in for positive reasons as well as negative. It is a source of confidence in the future as well as apprehension. I am somewhat concerned about the lack of knowledge on the subject.

I would like to read a paragraph from a letter from Mr. Nagel, Director of the External Research Staff of the Department of State—this is very brief—in response to a letter of mine.

I have recently heard from Mr. Bundy about your request for information about research in population growth and economic trends in Communist China. The amount of research in the relationship of population growth and other economic factors is very limited. As Mr. Bundy may have written you, the principal reason for the small amount of work in this field is the inadequacy of statistical information gathered by the Chinese Government.

I'm tempted to stop at that point because I think it makes an interesting stopping point. I suppose we could always send them a letter and ask them to gather more statistical information. Mr. Nagel's letter continues:

Another reason suggested by experts is the difficulty of making predictions on the Government's vacillating policy toward birth control.

I will stop reading the letter at this point except to say it lists a series of papers that have been written under various sponsorships.

I think that we can make many small policy errors in State Department affairs, and I say small even in the context of whether we should put another 20,000 troops in Vietnam, compared with the enormous errors we can make if we underestimate the capability of 600 million Chinese to develop scientifically. That is an error beyond any which we have been talking about. Having spent the last several hours this morning with Secretary Rusk, I am relatively up to date on this.

I cannot underestimate my own concern with this subject. I think it is very important that we extend some type of cooperative and helping hand to China in connection with scientific research, not research on weapons, but basic research that is of interest to scientists everywhere.

I see no evidence of this being done anywhere. Rather, I see evidence of alienating the Chinese scientific community, which I think in the long run would be an enormous mistake.

I will let go of that particular subject for a moment.

The policy control which exists in international organizations by the State Department is of interest to me. I have many acquaintances in the scientific community that serve on various international committees. Every type of scientific discipline has some international scientific committee. I have at times been unable to discern whether these individuals went to these committee meetings as, what might be called, international citizens representing their particular scientific discipline, or whether they went as representatives of the U.S. Government, or whether they were acting under State Department instruction.

Are there any rules which guide the behavior of such individuals at international conferences?

Mr. POLLACK. I think as a general rule, to which there may be some specific exceptions, that when we send representatives to an agency of the United Nations or one associated with it, which is receiving its support from congressionally appropriated funds, that our participation in this agency, the definition of the program which we will support and so on are a consequence of governmental decisions.

Now we also support participation in meetings of the international Council of Scientific Unions by providing funds for the travel of some participants and Government funds I think are used by the National Academy of Sciences to pay the dues in this organization. Scientists who attend these meetings do not attend them as Government representatives. They attend them as qualified U.S. scientists in a particular field. I am not aware of any governmental instructions being issued to these people or any requirement on their part that they adhere to U.S. governmental positions in such meetings. That is a broad separation.

Mr. VIVIAN. I am sure you are familiar with COSPAR?

Mr. POLLACK. Yes.

Mr. VIVIAN. I understand there is both an American and a Russian delegate to that organization. I gather they are there principally in the role of representatives of their respective governments rather than scientific representatives.

Mr. POLLACK. I don't think so. May I just turn to Mr. Packard for a bit of advice?

Mr. PACKARD. No; that is not true. I am Robert Packard, head of the Outer Space Affairs. COSPAR is a nongovernmental international scientific committee. Its bureau consists of five, I believe, scientists. There is nothing in its bylaws or charter which provides that two of these be one an American or one a Soviet. By practice in logrolling within the organization this has been the case, and the American and Soviet members of their bureau or executive committee have served as the two vice presidents of the organization.

Mr. VIVIAN. This is not by requirement but it does happen.

Mr. PACKARD. Really by the practicalities of the fact that the two countries that can make contributions in this are the United States and the U.S.S.R.

Mr. VIVIAN. Are there any other American members who are active in COSPAR?

Mr. PACKARD. At the last meeting of COSPAR there were something on the order of 107 American participants.

Mr. VIVIAN. What happens if they disagree with the nominal position taken by the vice chairman?

Mr. PACKARD. They are free in COSPAR to express their views on the scientific problems and in the corridors to express their views on anything else they see fit. The decisions of COSPAR as an organization are made by its executive committee and by its representatives voting in plenary session. The composition of COSPAR is the national academies of the countries who participate, plus some representatives from the international scientific unions. The American participant in COSPAR has one vote.

Mr. VIVIAN. Is it the vice chairman of the executive committee who is the decisionmaking agency, and the assembly—I am sorry, I don't remember the label——

Mr. PACKARD. A plenary session of COSPAR.

Mr. VIVIAN. What happens if the executive committee and the plenary session disagree?

Mr. PACKARD. The executive committee makes recommendations to the plenary session and votes are taken in the plenary session.

Mr. VIVIAN. What happens if the executive committee votes one way and the plenary session votes the other?

Mr. PACKARD. There is only one vote in the plenary session, and he is the same man. He is the representative of the U.S. National Academy of Sciences, which is the American institutional member of COSPAR.

Mr. VIVIAN. I think you have answered the question which I have. I would like to go on to the matter of cultural exchanges. What funds are provided directly from the State Department for cultural exchange in the scientific areas?

Mr. POLLACK. I will have to supply an accurate answer for you on that for the record.

Mr. VIVIAN. Is it in tens of thousands of dollars or is it in millions?

Mr. POLLACK. It is not in millions.

(The information requested is as follows:)

DEPARTMENT OF STATE, BUREAU OF EDUCATIONAL AND CULTURAL AFFAIRS

TABLE I.—*Grantees in physical and natural science fields* [1] *(July 1963 to June 1964)*

Area	Students		Teachers		Lecturers		Research scholars		Specialists		Leaders, foreign	Educational travel, foreign	Total	
	United States	Foreign	United States	Foreign	United States	Foreign	United States	Foreign	United States	Foreign			United States	Foreign
Africa		192	4		9				1	4	5	4	14	205
Other American republics	2	105	1	11	35	1	3	25	3	7	8	114	44	271
Europe	67	339	12	21	37	30	41	229	6	6	18		163	643
Far East	10	141	2	5	15	8	14	88	3	7	7		44	256
Near East		254	12	19	36	6	12	42	3	11	13		63	345
Total	79	1,031	31	56	132	45	70	384	16	35	51	118	328	1,720

[1] This table reflects the numbers of persons on new grants during 1963–64 as well as those on grants extended from a previous year, for which additional funds were obligated.

Under the Department's program, the cost of grants awarded to persons in the fields of natural and physical sciences for the 1963–64 year amounted to $5,915,000. Included in this amount was the cost of the grants to teachers and lecturers in science fields in the amount of $1,388,000. Excluded from the total cost was the financial support involved in postponed travel for 1,173 grantees in science fields who were permitted to remain in the United States to complete their work and were allowed to use funds from previous allotments for their return travel.

Mr. VIVIAN. You indicated that a certain amount of funds were provided to the National Academy of Sciences for its activities overseas. Does this funnel through NSF?

Mr. POLLACK. Well, the role played by the National Academy of Sciences in the exchange of programs with the Soviet Union and certain of the bloc countries are obtained by them on grant from the National Science Foundation which in turn is making its investment on the basis of advice obtained from the Department of State that we think would be in the national interest for such a program to be conducted.

Mr. VIVIAN. Has the National Academy of Sciences ever asked for more funds than were granted?

Mr. POLLACK. I just don't know, sir.

Mr. DADDARIO. Will you provide that for the record?

(The information requested is as follows:)

FUNDING OF EXCHANGES OF SCIENTISTS ARRANGED BY THE NATIONAL ACADEMY OF SCIENCES AND ACADEMIES OF SCIENCE OF THE U.S.S.R. AND OTHER COUNTRIES OF EASTERN EUROPE

During the last 3 months of 1957 the Department of State conducted negotiations with representatives of the Soviet Government headed by Soviet Ambassador Georgi N. Zaroubin to achieve the first U.S.–U.S.S.R. intergovernmental agreement on cultural, educational, and technical exchanges between the two countries. In the course of the negotiations, the principal U.S. negotiator, Ambassador William S. B. Lacy, informed the President of the National Academy of Sciences (NAS), Dr. Detlev W. Bronk, that the Soviet negotiators had proposed inclusion of a provision for exchanges of scientists to be worked out by the NAS and the Academy of Sciences of the U.S.S.R., and he asked for Dr. Bronk's comments and guidance concerning the proposal. In response to the Government's desire to include provision for interacademy exchanges in the intergovernmental agreement on exchanges, the NAS agreed to cooperate and such a provision therefore appeared in section IX of the so-called Lacy-Zaroubin agreement of January 27, 1958. It may be noted that this brought into being an exchange arrangement between the two academies of a sort previously suggested to the NAS by the Soviet Academy in 1955. The earlier proposal did not develop significantly, in part at least because of the Hungarian revolution of 1956.

The negotiation of an interacademy exchange agreement as envisaged in section IX of the 1958 intergovernmental agreement was delayed at first because NAS President Bronk was unable to travel to Moscow until October 1958 because of his health. In October, Dr. Bronk was able to go and, as a result of his discussions with Soviet Academy President A. N. Nesmeyanov, returned with a draft exchange agreement for consideration by NAS governing officials. Negotiation of the agreement continued slowly by mail through the following winter and spring, and the text was finally signed as of July 9, 1959.

Prior to Dr. Bronk's departure for the U.S.S.R., the Acting Secretary of State, Mr. Christian A. Herter, wrote to him on October 4, 1958:

"These exchanges are of considerable importance and interest to the United States. I want to assure you that the Department of State strongly supports whatever impetus you can give to establishing a sound program that will involve a significant number of scientific exchanges. We shall be glad to assist you in any way possible to expedite your conference."

Dr. Bronk was accompanied on his mission by Dr. Wallace Brode, Science Adviser to the Secretary of State.

FUNDING OF THE U.S.-U.S.S.R. INTERAGENCY EXCHANGES

It had been understood between the National Academy of Sciences and the Department of State that provision for an interacademy agreement within the intergovernmental exchanges agreement implied no financial support from the Department. Thus, the National Academy of Sciences turned to the National Science Foundation (NSF) for funding. The National Academy of Sciences submitted its first request for support of the program to the National Academy of

Sciences on April 6, 1959, by which time the terms of the Bronk-Nesmeyanov exchange agreement were evident. That request was based on estimated maximum expenditures of $467,000 for completion of all exchange activities in the 2-year period of the agreement. In response, the National Science Foundation, on September 2, 1959, granted the National Academy of Sciences $235,000 for the conduct of the exchange program for a period of approximately 1 year, effective July 9, 1959. Because a considerable leadtime was required before individual visits could actually commence, the goal of accomplishing half the activities provided in the interacademy agreement of 1959 was not reached at the end of the first year, July 9, 1960. Therefore, the National Academy of Sciences later proposed to the Soviet Academy that the agreement be carried beyond the original 2-year term and continued through calendar year 1961. In July 1960 the period of the National Academy of Sciences grant was also extended for an additional year, and it was subsequently extended again for 1 year more, to July 1962.

The extensions of the grant which had been based on estimated needs for the first year only reflect not only the delay in the beginning of travel of exchange scientists and attendant expenses but also the fact that a number of activities for which a need for funds was anticipated never materialized. Thus, the original grant of $235,000 maintained the exchange program for more than 2 years.

A considerably enlarged continuation of the interacademy program resulted from the negotiation in early 1962 of a new 2-year interacademy exchange agreement as part of a new 2-year intergovernmental exchanges agreement. Whereas the first interacademy agreement had been worked out, independent of the period of validity of the intergovernmental exchanges agreement, as it turned out, its conclusion coincided with that of the intergovernmental agreement for 1960–61. It was signed on the same date also, March 8, 1962, and it appeared as annex No. 1 of the intergovernmental agreement.

Meanwhile, in support of exchanges still in effect under the 1959 agreement, the National Academy of Sciences, in April 1962, requested an additional $45,675 from the National Science Foundation. That amount was granted for a period ending August 31, 1962.

In order to support activities under the second interacademy agreement of March 1962, the National Academy of Sciences requested of the National Science Foundation $260,110 for the first of its 2 years. The National Science Foundation, on November 9, 1962, granted that amount to the National Academy of Sciences for a period of approximately 1 year ending in September 1963.

In August 1963 the National Academy of Sciences submitted to the National Science Foundation a request for additional support in the amount of $282,676 for operation of the interacademy exchange program from September 1963 through August 1964. The budget estimate underlying this request was based on the assumption that most of the visits provided in the exchange agreement for 1962–63 would be made, and the National Academy of Sciences had obtained agreement from the Soviet Academy that individual visits within that agreement might be made through academic year 1963–64, that is, through June 1964. Toward the end of 1963, however, it became clear that the full number of visits provided in the agreement would not be made. Accordingly, in December 1963 the National Academy of Sciences revised its request of previous August downward from $282,676 to $218,662 for the same period, September 1963 through August 1964. The request was granted and the task order was extended through November 30, 1964.

In February 1964 the National Academy of Sciences and Soviet academies concluded a third exchange agreement, once again a part of a new intergovernmental exchanges agreement for 1964–65. To carry out the activities for the first year of the new agreement and to continue activities pending under the 1962 agreement, the National Academy of Science asked the National Science Foundation for $230,000 for the 15-month period from June 1, 1964, through August 31, 1965. That amount was granted in December for a period ending August 31, 1965.

In July 1965 the National Academy of Science asked the National Science Foundation for continued support in the amount of $272,375 for the period from September 1, 1965, through August 31, 1966. That request is now pending.

FUNDING OF EXCHANGES WITH ACADEMIES OF EASTERN EUROPE

In response to a recommendation of the National Academy of Science Advisory Committee on U.S.S.R. and Eastern Europe, the governing officials of the National Academy of Science decided that the National Academy of Science might properly inaugurate modest exchange programs with the academies of sciences of Poland, Yugoslavia, Rumania, Hungary, and Czechoslovakia. As a first step it was considered desirable for small delegations of senior scientists from one country to visit the other in order to survey current research, identify laboratories in which one's own scientists might profitably be placed for research, identify scientists of the other country who might be invited to ones' own country, and to discuss with officials of the other academy the conditions under which bilateral exchange arrangements might be worked out by the National Academy of Science and the other academy.

For initial delegation visits to and from Poland and Yugoslavia, the National Academy of Science sought support from the National Science Foundation in December 1963 in the amount of $15,960. The request was supported by Dr. R. Rollefson, Director of International Scientific Affairs, Department of State, who wrote, as follows, to Dr. Leland J. Haworth, Director of the National Science Foundation, on January 22, 1964:

"The Department of State supports the project as proposed by the National Academy of Sciences as being in the foreign policy interests of the United States and would, therefore, appreciate your giving favorable consideration * * * to supporting the request of the National Academy of Sciences * * *."

In February 1964 the National Science Foundation acceded to the National Academy of Science's request for $15,960 for a period from February 1, 1964, through August 31, 1964. This task order was subsequently extended through August 31, 1965.

In April 1965, in anticipation of initial delegation visits between the National Academy of Sciences and the academies of sciences of Rumania, Hungary, and Czechoslovakia, the National Academy of Sciences requested an additional $15,000 from the National Science Foundation. In June 1965 the National Science Foundation amended the earlier task order to reflect the additional sum and also to extend the entire task order through August 31, 1966.

In view of the concurrence of the Polish Academy of Sciences and the Yugoslav Council of the Academies in similar memorandums of understanding on exchanges and the anticipated commencement of modest exchange programs with them during the winter of 1965–66, the National Academy of Sciences is in the process of submitting to the National Science Foundation a request for additional support in the amount of $75,000 for these exchanges during the current fiscal year.

Mr. Vivian. I would appreciate its request and the history starting with the National Academy of Sciences initial request.

Are you aware that National Science Foundation or the National Academy asked for funds for cultural exchange programs considerably above the existing level?

Mr. Pollack. I am not aware of that. I don't believe that it has happened.

Mr. Vivian. Is there any provision made by the State Department for extensive international exchange of teachers of science?

Mr. Pollack. There is a program carried on by the Bureau of Cultural Affairs for the exchange of teachers, some of whom are in the scientific field, but again, to give you a precise figure how many of these are in the scientific field, I would have to go back and obtain the record on that.

Mr. Vivian. Are there any major programs for exchange of teachers irrespective of whether they are in the scientific field or not?

Mr. POLLACK. I think I would call them major, yes. Money is being expended on this purpose by the Office of Education and by the Department of State.

Mr. VIVIAN. I would appreciate a summary of those. I would appreciate having the scientific exchange delineated but not subtracted from the total.

Mr. POLLACK. Right.

(The information requested is as follows:)

DEPARTMENT OF STATE, BUREAU OF EDUCATIONAL AND CULTURAL AFFAIRS

TABLE II.—*Grants for secondary and university teaching (1963–64)*

Field of specialization	Teachers				University lecturers				Total	
	United States		Foreign		United States		Foreign		United States	Foreign
	New	Extension	New	Extension	New	Extension	New	Extension		
Physical and natural sciences	30	1	54	2	125	7	44	10	163	110
Social sciences	108	3	95	....	175	13	42	5	299	142
Humanities	243	21	76	26	110	10	95	22	384	219
Education	60	2	621	10	39	1	2	....	102	633
Total	441	27	846	38	449	31	183	37	948	1,104

NOTE.—This table shows only those grants awarded under the educational exchange program of the Department of State for secondary and university teaching. Other grants on this program are made to American and foreign college students, research scholars, specialists, and leaders. The Department also gives some financial support to organizations such as the American Field Service and the National Catholic Welfare Conference to assist their programs with teenage students from abroad.

These statistics are compiled on the basis of new grants (those which were awarded for the year 1963–64) and extension grants (those which were extended from a previous year). Included in the count for foreign extension university lecturers in the physical and natural sciences are 9 grants involving no additional expenditure.

PRINCIPAL EXCHANGE PROGRAMS CONDUCTED BY U.S. GOVERNMENT AGENCIES [1]

1. Department of State—Bureau of Educational and Cultural Affairs

Under the Mutual Educational and Cultural Exchange Act of 1961 (Public Law 87–256), known as the Fulbright-Hays Act, the Bureau administers an exchange program to increase mutual understanding.

(*a*) Makes grants annually to more than 2,300 U.S. citizens to go abroad and over 5,600 foreign nationals to come to the United States. Since adoption of the original Fulbright Act in 1946, over 26,000 Americans and more than 64,000 foreign nationals have participated in the program. Grants are made for university lecturing, advanced research, graduate study, teaching in elementary and secondary schools, practical experience in technical and specialized fields, and consultation and observation.

(*b*) Also has responsibility for a wide range of related activities, such as overseas tours by performing artists, music and drama groups, and athletes; bringing foreign leaders to the United States and sending out doctors, writers, coaches and other American "specialists."

2. Agency for International Development (AID)

(*a*) Participant training program: Brings approximately 6,000 foreign nationals to the United States each year for widely varying periods of time, for project-oriented training in agriculture, education, industry, labor, transportation, public administration, public health, etc.

(*b*) University contract programs: Sends U.S. university personnel overseas under contract arrangements with foreign governments and institutions to help establish and strengthen faculties, improve curricula, etc.; brings foreign faculty and students for training at U.S. universities.

[1] See "Explanatory note."

3. Department of Defense

(*a*) Military assistance program: brings approximately 18,000 foreign military personnel to the United States for training periods ranging from 2 weeks to 3 years; sends teams of U.S. training personnel abroad.

(*b*) Brings foreign Navy and Marine officers to the United States and sends U.S. officers to other countries for the purpose of standardization of naval operations.

(*c*) Ryukyus exchange program: Brings leaders and university students to the United States for observation and study; sends U.S. professors to assist in the development of the University of the Ryukyus.

4. Department of Health, Education, and Welfare

(*a*) National Institutes of Health:

(1) Brings young scientists and research trainees for training and senior scientists for collaboration with NIH personnel.

(2) Gives fellowships to American scientists for study and research abroad.

(*b*) U.S. Office of Education:

(1) Language development program brings foreign professors to teach at language institutes under the National Defense Education Act (NDEA).

(2) Language development program sponsors institutes for elementary- and secondary-school language teachers under the NDEA.

(3) Makes grants to advanced U.S. graduate students, preparing for college training, to study overseas under the Fulbright-Hays Act.

(4) Sponsors summer seminars for professional development in language and area studies, principally for secondary-school teachers, under the Fulbright-Hays Act.

5. National Aeronautics and Space Administration (NASA)

(*a*) Brings senior foreign scientists for advanced research at NASA centers.

(*b*) International University Fellowship Program brings foreign students for study and research in space science at U.S. universities.

(*c*) Brings foreign technicans for training at NASA centers.

6. National Science Foundation (NSF)

(*a*) Inter-American Exchange of Scientists Program: This program, administered by the Organization of American States (OAS) and partially financed by NSF, provides for the exchange of scientists between the United States and other OAS member countries.

(*b*) Exchanges with the U.S.S.R.: An NSF-supported program, administered by the National Academy of Sciences, provides for an exchange of scientists with the Soviet Academy of Sciences.

(*c*) Programs for American scientists: Grants for international travel for meetings and for exchange of information on scientific research; fellowships for study and research abroad.

(*d*) Programs for foreign scientists:

(1) Senior foreign scientist fellowship program brings senior scientists for visits to U.S. universities.

(2) Visiting scientists, brought to the United States by American scientific societies with NSF support for lectures, seminars, and consultations.

(3) Foreign scientists are brought to lecture in NSF summer institutes for U.S. secondary school and college science teachers.

7. Peace Corps

Sends qualified American men and women to interested countries to help meet their need for trained manpower, promotes a better understanding of the American people in those countries, and promotes a better understanding of other people on the part of the American people.

EXPLANATORY NOTE

The above listing includes those agencies conducting the principal programs under which Americans go abroad and foreign nationals come to the United States for educational, scientific, and cultural purposes. Many other agencies are involved in providing a variety of services for foreign visitors under these programs and in supplying personnel, principally to AID, for training programs abroad.

Mr. VIVIAN. With regard to the exchange, would it cover one teacher in a thousand throughout the world each year, or some larger or smaller figure?

Mr. POLLACK. I would think a smaller figure than that.

Mr. VIVIAN. In other words, 1 in 10,000, perhaps?

Mr. POLLACK. Possibly.

Mr. VIVIAN. Has any consideration been given to increasing that number by a very large amount?

Mr. POLLACK. I know that this prospect has been considered, but I have not been party to that consideration and cannot tell you how far it has gone.

Mr. VIVIAN. Can you tell me approximately who would have this information?

Mr. POLLACK. I would turn myself to the Bureau of Cultural Affairs, for this information, of the State Department.

Mr. VIVIAN. Not the Office of Education?

Mr. POLLACK. No. I may end up there before I could complete my statement.

Mr. VIVIAN. I am now in the course of trying to prepare a bill for submission to the Congress which would enormously increase the amount of cultural exchange of teachers in the United States, and I am having enormous difficulty finding out who has responsibility for this in the Government.

Mr. POLLACK. It was part of the origin of this piece of legislation which I knew had been under consideration, but I didn't know whether it had reached the state of legislative proposal.

Mr. VIVIAN. I would appreciate it if you could identify the participants so I can talk about them. I have no further questions.

Mr. ROUSH. How many countries maintain scientific attachés in this country?

Mr. POLLACK. I think our last count numbered about 15.

Mr. ROUSH. Are these for the most part the same countries in which we maintain a scientific attaché?

Mr. POLLACK. There is a fairly high correlation, but there are a few countries that maintain attachés here where we do not participate.

Mr. ROUSH. If a Government agency sends a delegation or a representative to an international meeting, does the State Department control the official statements of policy of those particular agencies in any way?

Mr. POLLACK. Yes, sir.

Mr. ROUSH. There is a requirement that they do coordinate with the State Department?

Mr. POLLACK. Yes, sir; there is, sir.

Mr. ROUSH. Even if another agency is sponsoring the program?

Mr. POLLACK. Yes.

Mr. ROUSH. I have no other questions.

Mr. DADDARIO. Mr. Pollack, what are the scientific attaché's capabilities to attend meetings which he believes are important, and what funds are provided to him? How restricted is he by the control of the embassy at which he happens to be stationed?

Mr. POLLACK. Mr. Chairman, I made a canvas of the attachés on that very point about 3 months ago, and I was myself surprised by the fact that the picture was as good as it apparently is. We have 16

countries in which we have attaché posts, and my recollection is that in about 13 of them our attachés had about as much money for travel purposes and attendance at meetings as they were able to devote their time to, and they were quite satisfied with their capacity to move about. In three of our posts the problem is still existent, and we are taking steps to see if we can improve that situation.

Mr. DADDARIO. Could you provide for the record more information on that?

Mr. POLLACK. Yes.

(The information requested is as follows:)

ATTENDANCE OF SCIENTIFIC ATTACHÉS AT SCIENTIFIC MEETINGS

The scientific attachés are authorized to attend any meetings which they believe are important and are related to their responsibilities or are within their general area of scientific competence. Funds for travel to meetings within the country of assignment are provided and controlled by the embassy. To the best of our knowledge none of the attachés have been denied the opportunity to attend such meetings.

For travel to meetings outside the country of assignment funds are allotted specifically for such purposes and administered by the embassy. During fiscal year 1964 61 trips were authorized for attachés to attend either scientific meetings or to engage in orientation travel outside their country of assignment.

Mr. DADDARIO. You mentioned NSF's role as far as its international participation is concerned and you envision for it a greater field of activity. Could you go into that a little further?

Mr. POLLACK. Yes; I would be glad to. I should make clear that I speak of an agency such as the National Science Foundation. This thought has not been pursued far enough in the executive branch for that to yet be our chosen instrument. But the budgets of the various departments and agencies that carry scientific and technical programs are generally built around the mission of the agency, the so-called domestic mission proper. They are in the process of putting together an annual or a projected plan over several years do so in terms of priorities that are developed essentially from their perspective of the domestic considerations which determine their pursuit of this course of action as opposed to that course of action. Secondly, each of these departments in town is by definition concerned with its own responsibilities. Essentially, it protects its own budget, it protects its own piece of territory so to speak, and there is I think a mutual diffidence about not getting into the other fellow's territory. We have many budgetary and legislative mechanisms at work here to keep the relative jurisdictions of the departments separate and distinct from each other.

Now, there are opportunities and there are requirements, and I am suggesting I think there are going to be more of them in the future than there have been in the past, where it will be desirable for the United States to pursue a scientific relationship, be it cooperation or what have you, that is neither related, per se, in the first instance to the priorities that have been established by the domestic agencies for the pursuit of their domestic purposes or that do not fit the jurisdictional territories and boundaries that have been established by the nature of the U.S. Government's organization. Now, in these cases it becomes a rather cumbersome and excessively complicated problem to organize the U.S. Government to respond to this kind of an oppor-

tunity. In the first instance, agencies don't feel, and it is understandable why they would hold this point of view, that they are authorized to spend funds available to them for this kind of activity. Second, it hadn't been anticipated in the development of their budgetary program. They have their own congressional committee to deal with, their own constituencies in the United States to take into account.

Second, if it involves more than one agency, it immediately gives rise to coordination and division of responsibility, and when you get to three or four you have all the complications and problems of committee management. I am suggesting in the statement that it would be desirable to have a way to deal with these opportunities that is more immediate and more direct and more responsive which would be to provide broad authority to the executive branch to engage in scientific endeavors for the benefit of science per se, for the benefit of the international status of science. I am not suggesting, necessarily, that were this responsibility to end up with an agency such as the National Science Foundation that they would undertake these programs and carry them on from that point forward. They might undertake to provide the seed money required to get the thing started until the normal budget process could relate this back again to the domestic agency most appropriate for the function. They might simply provide the funds to a domestic agency which already has the capability and the staff appropriate to the subject. But it would provide a way of dealing with two aspects of this problem: one, the lack of distinct authority, and second, to the question of providing multiagency participation when necessary.

I noticed this morning that Governor Harriman apparently had a talk with Vice Premier Rudnev, and he talked about cooperation in the scientific and technological fields, and Mr. Gross, who wrote this article, made the point that if the present Harriman contacts can open an effective dialog on matters unrelated to Vietnam it would be a significant gain. I would subscribe, I think, to that point of view. I do not know, at this point, what might come out of this kind of proposal, but it is entirely possible that the scientific cooperation might involve an activity that does not neatly tie into a single department or agency of the U.S. Government, and it might call for a participation or collaboration in an effort which, at this point in time, under priorities established by the domestic departments, they were planning to approach, a year or two hence. The international purposes that might be served by this collaboration, if put into the balance, might call for this priority to be moved up and this problem to be approached at this point in time. This is the essence of my point.

Mr. DADDARIO. I hope we will be able to send additional questions to you, Mr. Pollack.[1] We have a rollcall vote; otherwise, we would continue. I would like to commend you and your staff for coming here this morning to be with us.

This committee will adjourn until tomorrow morning at the same place at 10 o'clock.

(Whereupon, at 12:22 p.m., the subcommittee adjourned to reconvene at 10 a.m., Wednesday, July 21, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JULY 21, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order.

Our first witness this morning is the very distinguished president of the University of Notre Dame, Father Theodore M. Hesburgh. We are pleased to have you here, Father Hesburgh, and especially so because of the fact that you have served for many years as a member of the National Science Board. This is particularly important as we review the activities of the National Science Foundation. We are anxious to hear from you.

Mr. Roush. Mr. Chairman, coming from Indiana, I especially want to add a word of welcome to Father Hesburgh, and to tell the other members of the committee that Notre Dame has achieved new stature under the leadership of this distinguished man. I am especially proud that he is here testifying before our committee.

STATEMENT OF REV. THEODORE M. HESBURGH, C.S.C., PRESIDENT, UNIVERSITY OF NOTRE DAME

Father Hesburgh. Thank you, Mr. Roush, Mr. Daddario, gentlemen.

I appreciate very much the opportunity to take part in these hearings which I judge to be most important. As you know, for the past 11 years I have had the privilege of serving as a member of the National Science Board, and also, for the past 13 years I have been president of the University of Notre Dame. I am sure it must be evident to you that because of each of these two associations, I have had a deep and continuing interest in the activities of the National Science Foundation. But over and above these, as an educator and as a citizen of this country, I have observed the growth and development of the Foundation with great satisfaction—for I believe that it has exerted, and will continue to exert, an important and beneficial influence on our science and technology and on the education of future scientists, and, through these, on the welfare of our Nation as a whole.

I believe that all of us have reason to be grateful to those who conceived the concept of a National Science Foundation, to those who en-

acted the wise legislation which created it and to those who have sympathetically supported it during these first 15 years of its life. These have included, of course, not only Dr. Vannevar Bush but also four Presidents of the United States and a great many Members of the Congress.

As you know, the Foundation is comprised of a National Science Board of 24 members, appointed by the President, and the Director who, ex officio, is also a full member of the Board.

The National Science Foundation Act assigns policy determination to the Board. The Director, appointed by and responsible to the President, is the chief executive officer of the Foundation as well as a member of the Board. This is a unique organizational structure among Federal agencies and seemingly includes a division of responsibility which might, to some, appear to be theoretically unwise. However, I can bear witness to the splendid cooperation which has existed between the Board and the Directors—first Dr. Alan Waterman and, during the past 2 years, his capable successor, Dr. Leland J. Haworth. I can testify, from 11 years of personal experience, that the Board and the Director, working cooperatively and harmoniously toward common goals, have indeed been the Foundation as the act prescribes they shall be.

The original version of the NSF Act stated that no final actions relating to the award of grants or fellowships might be taken unless, in each case, the Board had reviewed and approved each such action. However, the act as amended in 1959 permits the Board to delegate to the Director this authority of review and approval.

During the early years of the Foundation, it became obvious that the Board should not concern itself with all of the many individual actions which are necessary. Accordingly, it has delegated such authority to the Director and limits its own review and approval activity to those matters that involve special policy considerations or very large sums of money. The Director and his staff, on the other hand, have always taken pains to keep the Board well informed in detail of all the actions taken under the delegated authority.

The Board, on its part, has concerned itself increasingly with more general policy matters relating to strengthening of the scientific research and education of the country. To this end, about a year ago we revised our committee structure to permit more effective policy consideration. We now have three principal standing committees in addition to the executive committee.

One of these is charged with consideration of policy matters relating to substantive, programmatic areas of science and education. Another is concerned with policy problems which arise from administrative considerations, particularly those connected with Foundation-university relationships. The third committee deals with long-range program and policy questions pertaining to the role of the Foundation, in the context of the total Federal and national picture, in research and education in the sciences.

Although this committee structure is relatively new, it is already showing its usefulness. The committees meet frequently and are able to give deep and careful consideration to specific policy questions. Their findings and conclusions are reported to the Board which then has a basis for taking well considered action. With the Board

freed of much of the detail work and with a mechanism for policy consideration and formulation operating so well, I believe the Board will be an even more effective instrument for development of measures to strengthen our country's science enterprise.

I should like, Mr. Chairman, to turn now to some of the substantive aspects of the Foundation's operations. I shall not devote much time to discussion of the support which the Foundation provides for basic research through its project system, its facilities grants, institutional grants, the national centers, and so on. I believe there is common agreement that this support has had an enormous beneficial influence on the growth and development of our national science enterprise. The Foundation's influence has been most pronounced, of course, on our basic research effort which is to be found largely in our universities. The very act of creating a national agency devoted to basic research has lent a new prestige to this field of activity. Its nourishment though generous—though still inadequate—appropriations which were wisely administered permitted marked expansion and increased productivity. It is in considerable measure for these reasons that our basic research enterprise today is the envy of all the world. It is factors such as these which are responsible for our recent production of such a large proportion of Nobel Prize winners. And, to a considerable degree, these are the reasons behind the current strength and vigor and high level of excellence of our entire national scientific enterprise. Obviously we can all derive great satisfaction from this situation. I can assure you, Mr. Chairman, that I do.

I believe we all agree on these points and there is no need for me to belabor them. However, I should like to dwell for a moment on the Foundation's support of social science research.

One of my early assignments as a member of the National Science Board was to chair a Board committee on the social sciences. This, coupled with my own background training and interests, has led me to follow these activities very closely and with considerable attention.

I single out the social science activities for comment not only because of the high regard I have for the Foundation's role in this field, but also because it has come to my attention that during previous sessions of these hearings some of you have evidenced considerable interest in this phase of its activities.

Although the act does not specifically enumerate the social sciences as it does the natural sciences, it does include authority to award grants and contracts for basic research, as well as fellowships, in what are referred to as "other sciences." The report on the bill which became the National Science Foundation Act, and its legislative history, clearly indicate that it was intended that the Foundation should explore the needs of the social sciences and take appropriate action with respect to them.

In 1953, the Foundation began to study what its proper role might be with respect to the social sciences. A limited research support program, begun in 1954, has been gradually and cautiously extended. In 1960 the Board approved the establishment of a Division of Social Sciences. This is coordinate with the other research divisions, and now supports research in anthropology, economics, psychology, sociology, political science, geography, and linguistics. Current obligations for research grants in the social sciences are at the level of about $10 million per year.

As research support in the social science fields has grown, so have the social science aspects of the Foundation's education, training, and other science support efforts. The programs which provide fellowships for graduate students, and those which support curriculum studies, science information activities, construction of laboratory buildings and facilities, science development awards—all are open to the social sciences just as they are to the natural sciences.

This experience has demonstrated that the same agency can indeed support the social and the natural sciences. Although the problems and methodologies differ from field to field, the objectives and intentions are similar. In all these fields, fundamental research is principally university-based and the standards and criteria are very much alike.

The same decade that has seen the Foundation expand in this area has seen the Federal Government as a whole become more involved in the areas of social science concern. We are all familiar with these. The problems of arms reduction, of population increase and mobility, of urbanization and of urban renewal, of equal rights and equal opportunity, of poverty and of peace—all of these and many other social problems are major concerns of our Government. Many new programs directed toward amelioration of these pressing social needs have been developed.

The Foundation's support of basic research in the social sciences has helped to serve as a valued adjunct to these efforts. It may be difficult for some to see the immediate connection between an experimental study of human communication and increasing the possibility of peace in the world, or between an econometric model of the economy and learning how to prevent a recession or inflation.

However, the potential is there and basic research in these fields, as in others, provides understanding which, in the long run, will surely have a great impact—and particularly so in proportion to its initial cost.

In short, I believe it important that the Foundation has developed its social science support programs and that these operate in the same way and by the same principles and criteria as do the natural science programs.

It is important that support of fundamental academic research in the sciences has been provided on a broad, nondiscriminatory base and that this has helped to give recognition and status to the social sciences as legitimate areas of research. The development of such areas into full-fledged fields of scientific exploration is a most significant contribution, and in my belief, should be continued and expanded.

I should like to mention several of the Foundation's educational activities which, in my view, are of very great significance to our national interest. One of these is its program of fellowships, supplemented more recently by a traineeship program. These have proven to be highly effective means of insuring the future scientific strength of the Nation by providing opportunity for our young people of highest ability to continue advanced training in science, mathematics, and engineering. I want to stress particularly those programs which are directed toward graduate students—the young people who have completed their bachelors work and have turned to pursuit of an advanced degree, the masters or the Ph. D. The Foundation's graduate fellow-

ship is a form of grant to such an individual, selected in a national competition on the basis of ability and promise.

The graduate fellowship program permits the student to pursue that field of science which interests him most. It is based on the well founded premise that students at this educational level know quite accurately in what subject matter areas they wish to build their careers.

Accordingly, fellowships are awarded—after national competition—on the basis of merit and ability without assignment of quotas by field or discipline. Only in cases of substantially equal merit do considerations such as discipline or geographical origin enter the picture.

In talking about the graduate fellowship program, Mr. Chairman, I have referred to merit, ability, and promise as criteria for selection of fellowship recipients. Speaking as a university president, I can verify that the Foundation's fellowship awards have been made to our most able graduates. And this is as it should be. Those who framed the National Science Foundation Act directed that fellowship recipients should be selected on the basis of ability. I believe this was a wise decision because if we are to provide the Nation with the best possible scientific talent, it is mandatory that we assure our most able and best trained young people the opportunity to work toward this end.

The act also directs that the fellowship recipients shall be permitted to attend the institutions of their choice. As a consequence, they tend to select those institutions which are most outstanding in the quality of their offerings for training in the sciences. This is understandable, and is in the best interests of the Nation. These high-ability young people deserve the best possible opportunity to complete their development into mature scientists. However, it is clear that the resultant concentration of graduate students at a few institutions does not contribute directly to the development of graduate education at other institutions. Recognizing this situation as a further responsibility, the Foundation has sought means to extend the geographical and institutional distribution of high-ability graduate students. A principal effort in this direction has been the introduction of the traineeship program which differs from the graduate fellowship program in several ways. One is that the university, rather than the Foundation, selects the award recipients. Also, in the traineeship program, the Foundation decides, within limits, on the distribution of awards among the various fields of science. Both these effects are achieved by permitting the university to apply for the number of traineeships it believes it needs for each of the several eligible fields of science. The Foundation then evaluates these requests, taking into account the resources for graduate training of each such department as well as the capacity of the department to increase or accelerate its output of graduate students. On the basis of such evaluation, specific numbers of traineeships are awarded to each of the approved departments. Thereafter, the department and the institution deal directly with the student applicant and the selection remains a local one.

The traineeship program is much newer than the fellowship program and we have not had as much experience with it. However, I am confident that I reflect the belief of my fellow Board members when I say that we heartily endorse this second, but by no means inferior,

mechanism for assisting in graduate science education. Through this means the Foundation is able not only to broaden its geographical and institutional distribution of funds and to assist in the development of graduate education at a larger number of institutions but also it is enabled to respond to immediate and short-run demands for additional trained manpower in particular scientific fields.

In speaking of the fellowship program, Mr. Chairman, I have concentrated on the education of young people seeking training toward the masters and Ph. D. degrees. I have not touched on the several programs for postdoctoral scholars and for summer study or research of teaching assistants. These, too, are important and worthy efforts. Of particular significance, I believe, is the program of science faculty fellowships which enables undergraduate teachers at the smaller institutions to make progress toward their own advanced study or to obtain much needed intermittent refreshment and updating on scientific subject matter.

These fellowships permit more mature scholars to intermingle study with teaching and research. They are particularly profitable in that they assist in a material way to improve the quality of science teaching at our smaller institutions of higher education, especially those which are less heavily involved in research.

Mr. DADDARIO. Father Hesburgh, you stress the importance of intermingling study with teaching and research. We have had during the course of these hearings some concern about the fellowship recipients not becoming sufficiently involved in teaching. There has been some attempt made to develop this further and there has been, for example, the authority allowed to the universities to grant them up to a certain amount of money as an inducement to teach.

What has been your experience with that, and do you think the situation might be improved?

Father HESBURGH. My experience is a personal one at our own university, but what we have found as a general rule is that it is not good to have first-year graduate students teaching. In other words, there is a break between high school and college, there is a break between college and graduate school, and as general rule of thumb we greatly discourage and rarely permit first-year graduate students to teach. As they get on to their second and third year, we think a little teaching is a good thing. First of all it gives them a little of the drama of teaching and induces them to get interested in the teaching profession, and, secondly, they are more qualified to teach at that time. But here, too, there is a danger, if you get them too involved in teaching, then they will never get on to the finishing of their research and their dissertation work. I think one of the greatest needs in graduate students in all departments today is to get students through. Some students become perpetual students, and there are times when the institution somewhat fosters this by using them too much for teaching when they should be studying and doing research. So our own particular experience is that we greatly discourage any teaching in the first-year graduate studies, we permit it only to a lesser degree in the second and third year, and try to stop it during the dissertation year so they get finished and get out and get to work in teaching and research.

Mr. DADDARIO. Do you find there is a desire within this group to teach or is it something that needs to be given some impetus?

Father HESBURGH. I think it needs a little encouragement. I would be for all graduate students teaching at some time in their career, because there is only one way you get to love teaching and that is by teaching. I believe there is a great deal of glamor surrounding research nowadays, which is understandable, the excitement of finding new knowledge, of participating in the joy of discovery, but at the same time there is also a great joy in bringing minds to life, and this is the joy of teaching. I would hope that a student in all of our graduate schools would get some experience with both of these experiences because they are both important in the total maturing of a graduate student.

Mr. DADDARIO. How has the formula worked out at Notre Dame? Have you had sufficient experience so that you can trace it?

Father HESBURGH. I would guess that the great majority of our graduate students go into teaching except in some areas. There are some areas of chemistry and some areas of engineering in which there is a great need for people in industry and they get attracted there. I would think that most of our people in mathematics, physics, biology, and in some theoretical science such as metallurgy would go into teaching, and I think we take an attitude as a graduate school that we are hoping our greatest contribution, our reason in a sense for being engaged in this is to provide good teachers for the country. This doesn't mean the lack of desire to provide good people in research, too, because this is an important component of good teaching, particularly in the sciences.

Mr. DADDARIO. Thank you.

Father HESBURGH. I will continue now.

Another group of Foundation education activities which have always been close to my heart are those concerned with improvement of education in the sciences, mathematics, and engineering. These consist of a group of programs designed to improve each of the two fundamental factors involved in education; namely, the effectiveness of the teacher and that of the subject matter which is taught.

As you gentlemen know, these programs collectively are of impressive size, both in dollar expenditure and in number of persons affected by them. The number of teachers who have received additional training is large. The number of students affected indirectly is enormous. These programs have reached into every corner of our country with a major impact at the grassroots level. We do not need to guess about the results. They are self-evident; for example, in the vastly improved preparation with which students enter college—so much improved that our beginning college courses in science have had to be revised to higher levels. What this means, of course, is that our young people are learning much more and more quickly and, therefore, are better prepared than ever before.

One of the most notable of the Foundation's innovations is the so-called institutes program which is aimed at improving and updating of the teacher's substantive knowledge of the field of science being taught. It is to be remembered that knowledge in the sciences has been increasing at an enormous rate. In many cases, the teacher's

last training in the field was taken 10 or 20 or even 30 years ago. It is understandable, therefore, that many such teachers, whose training dates from another era, find it difficult to teach the science of today.

Accordingly, the institutes supported by the Foundation are designed to assist the teachers to catch up and to update their own knowledge of recent developments in their fields. Over the years, these institutes have been heavily concentrated at the high school teacher level—a concentration that has been quite conscious and deliberate on our part. For it is in the high school that science first appears in the curriculum in the form of specific courses taught by special teachers. Therefore, the high school is not only a crucial point in science education but, also, it is the stage of the educational process in which the greatest and most effective impact could be achieved rapidly by teacher improvement.

It is important that students be subjected to good teaching at the earliest possible level. Education is a cumulative process, each level building on the previous ones. What can be taught at one level is determined to a considerable extent by what has been already taught and how it has been taught at earlier stages. This is most clearly exemplified by mathematics, which is a separately identified subject as early as the first grade. It is even more cumulative in character than some of the other subjects and it is studied by all students for a number of years. Furthermore, a mathematical foundation is necessary for most other fields of science—and a knowledge of mathematics is useful in all walks of life. Hence, the Foundation's teachers institutes have consciously given special attention to this subject. Indeed, in the case of institutes for elementary school teachers, those devoted to mathematics predominate.

Effective as the teacher institutes may be, however, they do not solve all problems. I remind you that in the institutes programs the teachers apply as individuals and are selected as individuals. This, we believe, is as it should be. But it is a fact that something like half of the high school teachers of science and mathematics have never even sought admission to any of these teacher programs. Also, there is a continuing stream of new teachers entering the classroom and many of these have had less than adequate preparation at the outset. Much will have to be done about these matters. The Foundation is seeking intelligent ways to help with them. There are no easy solutions to such problems but the search for them continues.

While speaking of improvement of science education, I should mention that, in addition to increasing the knowledge and ability of the teachers, it is important that they be provided with the best possible modern, up-to-date curricular materials and aids. I refer to textbooks, laboratory manuals, movie filmstrips, laboratory equipment, demonstration materials, and so on. These are being given serious attention by the course content improvement programs of the Foundation with notable success. I believe that the college physics professors of the country, for example, would heartily agree that since the introduction of the so-called physical science study committee high school physics curriculums, many students come to college enormously better prepared in physics than ever before. The same is true for chemistry, biology, and mathematics and now it is spreading to other fields. This, too, has contributed much to the educational revolution which has oc-

curred in the last 8 to 10 years. I am proud that, in large measure, the Foundation was responsible for these advances.

Time does not permit discussion of all of the Foundation's science education programs. I have mentioned only a few. But I may say that all of them are aimed at a single objective which is to assure our young people the maximum opportunity for development of their scientific potential. This is a worthy goal. It is my belief that these programs are doing a great deal to help us reach that goal.

Mr. Chairman, in the final portion of my testimony I should like to touch upon an area which, I am sure, is of interest to your committee. I refer to the relationship between the Foundation and the institutions of higher education—the universities and colleges of the country. I believe it is safe to say in this connection that, in the main, these relationships have been harmonious and beneficial both to the institutions and to the Government. The Foundation is held in high esteem by the institutions of higher education and by their faculty members. It is considered a real mark of prestige and accomplishment to receive a Foundation grant. This is so because it is known throughout the academic world that the Foundation gives careful and fair evaluation to every request and that, within the limitations of the funds placed at its disposal, it attempts to support those of the highest quality. Of course, with many more requests than it can support, there are many disappointed proposers of projects. But, on the whole, even those who are thus disappointed agree that the procedures and consideration have been fair and that the administration is honest and just.

Many persons in academic circles would like to see the Foundation receive larger appropriations so that it might support a larger proportion of the worthy projects submitted to it. It is recognized that although the Foundation's budget has grown considerably in these first 15 years, it has not grown sufficiently rapid, particularly if one bears in mind that it is the only Federal agency with responsibility for nonmission-oriented basic research and for the welfare of education in the sciences.

Of course, the philosophy of supporting the highest quality projects results in a considerable proportion of the grants being awarded to a few institutions. Although this is understandable, nevertheless it tends to create the problem of geographical, or, more correctly, institutional concentration of funds. This is a matter which has been of concern to many of us who are involved in the university life of the country just as it has been of concern to this committee. We must continue to seek ways by which we can alleviate this situation to some extent. But it is obvious that simply dividing the available funds on a formula basis without regard to quality is not the way to do it. We must strive to achieve two goals. The first is to maintain and nourish those centers of high quality in research and education that already exist. Surely, it will not be to our advantage to cut the peaks of quality down to those of lower level. These high-quality institutions not only provide a goal toward which the others can aspire and work but also they are the sources of the teachers and researchers who, coming to the less well developed institutions, will help them to improve their own level of excellence.

Our second problem is to assist, wherever we can, the attainment of higher levels of excellence. This, it seems to me, promises the greatest possibility of alleviating the problem of institutional concentration of funds. And this is why all of us on the National Science Board are so enthusiastic about the Foundation's new activity which we call the science development program. This program, which has just completed its first full year of active life, is designed to assist universities to develop groups of science departments to a higher level of quality. The institution must demonstrate that it already possesses a reasonable nucleus of quality in the areas to be developed and that it has the will, the resources and the planning required to maintain them at the higher level which the Foundation grant will help them to achieve.

Already, during this last year, the Foundation awarded such science development grants to 10 institutions in various parts of the country. As you know, it is intended that during the current fiscal year another group of institutions will be helped. Thus, over a period of a few years, centers or nuclei of quality can be built where previously only potential existed. I believe this program holds great promise for the institutions of higher education and, through them, for the country as a whole.

Mr. Chairman, as is evident from my remarks, I am very proud—of the accomplishments of the National Science Foundation during its first 15 years. I believe that its establishment 15 years ago acknowledged a new dimension in the concern of the Federal Government for a previously largely ignored but most important segment of our national life. This acknowledgment has borne a very rich and beneficial harvest of direct and indirect consequences. Our research enterprise has been enormously strengthened. Basic research, the very foundation of our applied technological progress as well as of our understanding of man and his environment, has been given a respectable place—the place it deserves and must have.

Our scientific and technological establishment is now the strongest of all the nations of the world. Our educational enterprise has been accorded renewed recognition and consideration and, in the sciences and mathematics, has been given vigorous stimulation toward improvement. This now is being carried over to nonscientific areas with great benefit. The teachers of the country, once looked down upon, are more and more being recognized for the important role they play with the result that we can hope that additional first-rate people will make this field of activity their career choices.

In all these beneficial accomplishments, the National Science Foundation has played an important role. I can say to you most sincerely that I am proud to have been a member of its Board during 11 of its 15 years and to have thus been associated with its accomplishments. All of us look forward to the continued success of the Foundation in the important role it has to play in the future. And all of us sincerely hope that in the years ahead the Foundation will continue to enjoy the same fine support of Congress that it has had in the past.

I should not conclude this without thanking each of you gentlemen for your wonderful interest and the time you are spending to understand this enterprise because I think it one of the most important in our country.

Mr. DADDARIO. Father Hesburgh, would you describe in more detail the relationship of the National Science Board to the Director? How often do you meet? What is your relationship? What kind of staff help do you get, and where do you get it from?

Father HESBURGH. I would be very happy to do that, Mr. Chairman.

The relationship has changed somewhat over the years because, as you gentlemen can imagine, 11 years ago when I first went on the Board we had a budget, if my memory serves me well, somewhere in the area of $6 to $8 million, and now, as you know, we are creeping up on a half billion dollars, maybe not creeping.

But in any event it was a different kind of operation in the early days because we could meet roughly once a month, we could look at every single activity the Foundation was doing. There was not the sweep of different projects, and all of us I think on the Board in those days felt it was like running a corner drugstore where everybody that worked in the store knew what was going on.

As that budget started to grow, and, of course, it took an enormous jump after sputnik, as did many other science and research and educational activities, then we somehow had to change the balance, in our activities. We decided to leave to the discretion of the Director grants for projects up to a certain amount of money, a quarter of a million dollars. The Director would then report to us what activities he took upon himself to decide between board meetings.

This was, I believe, a wise move because it allowed us then to get into what you might call the areas of basic policy, looking into such specific things as university-Government relationships which, as you know, is a very important policy matter for the Government and for the universities and for the growth in science and education.

I happen to be vice chairman of the new Committee 3 of the Board. We meet every month. We comprise one-third of the members of the Board, eight members. We call ourselves at times the blue sky committee because we are trying to look ahead 10 years, first of all to assess what we have done in the way of large scientific endeavor and then where we should be going for the best growth of the Foundation.

In this way, instead of sitting down and looking at this grantee of the Foundation and this small research grant for $10,000 and this little thing here, we are looking at the broad issues which we think the Congress intended when it created a National Science Board.

To get specifically to your question, the relationship between the Director and the Board, I have mentioned the historical genesis of our relationship, where in the past before the law was amended the Director was ex officio, a nonvoting member of the Board. There were 24 members of the Board plus the Director who always sat with us but did not have a vote.

I think the Congress did a good thing in making him a full voting member of the Board and chairman of its executive committee, and I can say that it did not affect our relationship in any way whatever because we always had in this particular activity of the National Science Foundation Board a very fine relationship between the Board members and the Director, and making him actually ex officio, a full voting member of the Board, did not seem to affect that relationship at all.

I serve on a great number of boards and I think it is just a matter of administration that there is always in almost every human organization, be it a university or a business organization or any type of human organization, a bit of tension between the man who is actually the chief executive officer, the director, if you will, and the people who establish basic policy.

I can honestly say of all the various boards I have had the privilege of serving on, there is none which has operated with as much amity and accord and real discussion and consideration of basic policy than the National Science Board. When I joined the Board, I didn't think it possible for 24 people to have a discussion. It seemed like too many people, and there have been discussions over the years that maybe we ought to cut down the number of members on the Board. The fact is that the work gets done. I think it gets done with some intelligence and some wisdom. I wouldn't want to say that we don't make any mistakes because I am sure you do and we do at times.

Mr. DADDARIO. Congress also has been known to make mistakes at times.

Father HESBURGH. The fact is this association has been a fruitful one. It has only involved two Directors, Dr. Alan Waterman in the earlier days, and in the last couple of years Dr. Leland Haworth, and I would guess you would have to look very far to find a better operating relationship between an operation and the policymaking board than this one.

Mr. DADDARIO. These special committees meet once a month?

Father HESBURGH. That is correct.

Mr. DADDARIO. How often does the Board meet?

Father HESBURGH. We used to meet once a month. Now with the establishment of these special committees and the delegation of authority we find we can meet with the director less frequently, I would say six times a year.

Mr. DADDARIO. Whom do you look to to prepare information?

Father HESBURGH. This is the staff. We get so much information that again I don't know of any outside activity that I have where I have to do more reading than for the National Science Board.

We have enormously well prepared papers. I would say every time we come to the Board meeting, we have a stack of papers about 4 inches high. People are very good about doing their homework, and the staff working on the Foundation has always been first-rate to my knowledge.

If we want special information, for example, on these special committee meetings, all we have to do is ask the staff people, the appropriate staff person through the Director of course, for this information and we will have well prepared booklets on any subject regarding the Foundation's activity.

Mr. DADDARIO. Is there any problem because you get this information from the same people who are in fact advocating a position? Does it give you as a member of the Board, or does it give the whole Board, the kind of objective preparation that it needs?

Father HESBURGH. I have never felt that problem, Mr. Chairman, for this reason. This has been a very dynamic activity. It has grown very well, but in the early days we kept the brakes on, if you can believe this, so we could feel our way in these great areas of activity,

so that we could grow organically and not like Topsy in every direction at once.

When the time came to expand in this or that activity, such as course content or institute work or this or that particular type of activity, atmospheric science, which you will hear more about, or radio astronomy or something else, we always got a good number of alternate possibilities.

I think this has been where the staff has been most helpful to us. They rarely come to us and say we just want to do this. They say here are several new programs. We have a chance to discuss these programs, to judge for ourselves which ones we think are best, and I would say that it is a reasonably rare thing that the staff comes to us as advocates. They normally come to us with the best and most intelligent shopping list that they can find of what we are trying to get done, and we have considerable freedom in making up our minds as a board as to what programs we think are best.

The only real problem, as I said, with an activity this broad is to try to stay on top of all of it, and I must say we have been enormously well informed.

Mr. DADDARIO. What is your view, Father Hesburgh, as to the distribution of the scientific disciplines on the Board? Is it balanced sufficiently?

Father HESBURGH. This is a difficult problem in some ways because, as you can understand with a board that renews one-third of its membership every couple of years. It is quite difficult to get an even balance, and I think it would be preposterous of me to say that we are always in the best possible balance.

If I could tell you a funny story. When I first got the call from the President's office about whether or not I would accept membership on this Board, I told him I thought he had a mistaken idea, that my background had been mostly in philosophy and theology and somewhat in social science and not in the physical sciences at all.

Speaking of background on the Board, President Eisenhower at that time said he wanted someone on the Board with a philosophical and theological point of view. I didn't know exactly why, but I couldn't argue with him, so I said all right, and I have found that the Science Board has provided me with an enormous education in the whole sweep of modern science and basic research in our day. While we do have people on the Board who are highly qualified in physics, chemistry, biology, mathematics, and the social sciences and the various areas that we cover, we are not without some expertise in any of these areas. The main expertise we have is a total interest in the scientific and research endeavor.

It would seem to me that what you would want on this Board is not highly trained specialists, although we do have these—we have a Nobel Prize winner in biochemistry and that sort of thing—but what you really want on that Board is people who will take public responsibility with some background and knowledge and expertise on the total scientific effort as regards education and research. You really want some vision and depth and some concern for education and research.

Mr. DADDARIO. As you have moved ahead over the course of these years and enlarged your activities within the scientific community, how have you seen the National Science Foundation's relationship with the National Academy and OST and PSAC develop?

Father HESBURGH. That is a pretty big one to answer, Mr. Chairman. Let me try.

First of all, we have always had very amicable relations with the Academy. I suppose that one reason is that during the early years I was on the Board our Chairman at that time, Dr. Detlev Bronk, was both the president of the Academy and Chairman of the National Science Board for a period of time. There are very few Detlev Bronks in this country, but he was able to pull it off I think, and during that time we all got to learn more about the Academy.

I believe the Academy has a very strategic role to play in this country and of course it is much older than the Foundation, and I think in many areas where we have needed objective guidance the Academy has certainly played a very important role in giving this intelligent guidance.

I think most recently in the whole area of high energy physics the Academy has performed an enormously useful role in bringing about 30 of the top universities in this country into a national organization for the prosecution of high energy physics and the management of a 200 Bev. accelerator facility. Only the Academy could have done something like that.

I would say that our relationship with the Academy as far as I am concerned as a Board member, it is a place you can always turn to for objective and wise advice of the highest order, and that it has increasingly over the years played a very important role in the growth of scientific research, and I would add, a scientific point of view on where this country is going in all areas of science, because it comprises in its membership the cream of our scientific talent.

Now regarding the other activities I haven't felt any great tension. I think I could say as one thing that might be informative of the members of this committee that in the days following sputnik and in the days when we had to move quickly to upgrade scientific education and research in this country, especially basic research, we got enormous support from the President's science adviser, whether you refer to Mr. Killian or Dr. Kistiakowsky or Dr. Wiesner or presently Dr. Hornig. I found that these people looked upon the Science Foundation as a center for moving forward in scientific education and research, and they were very helpful to us in projecting our program and of assuring us of the full backing of the Office of the President. There were many times we moved forward more expeditiously and I hope more intelligently than we could have without their support. With PSAC and the Federal Council and all the other agencies, this often gives us a very good sounding board for decisions we must make. For example, to show you how interlocking these activities are, recently there was the Academy report on ground-based astronomy which was of great interest to Committee 3 of the Foundation's Board. First of all, we had something to talk about because the Academy had projected this written report. Secondly, this report was discussed by all of the Federal Council, which was again most helpful to us because it gave us some idea of how the total activity in astronomy was divided throughout the whole Government and how we could perhaps eliminate overlap and decide who could possibly take on the organic growth of astronomy for the years ahead to be sure we didn't drop behind, which is very important in the space age.

Thirdly, when we came down to decide what the Foundation's role was, we didn't come to this subject completely without information because we had a fine report, we had the reaction of the Federal Council to it, we knew what the general reaction of the Office of the President's Science Adviser was, and we could come with our own responsibility as Board members to say what the involvement of the Foundation should be in our judgment, and this was referred to the whole Board. To summarize in one word, I would say our relationship with these other bodies has been one of cooperation and as far as I am concerned fruitful cooperation.

Mr. DADDARIO. Mr. Roush.

Mr. ROUSH. Father Hesburgh, I am of the belief that the national interest is better served if we had a better geographical distribution of our research and development funds which come from the Federal Government. Would you agree with that?

Father HESBURGH. I would agree with one qualification. I think that what you express, and which I would agree with, is an ideal, and I think one of the key problems of the National Science Foundation is to work toward this ideal. When I say it is an ideal, I put it that if we could all close our eyes and say this is the scientific and educational structure of this country, it would be great to have strength in every part of the country, but the simple fact is for many casual historical reasons that are very hard to plot you get centers of excellence all over the country, and science is no exception, and science education and research is no exception. For example, in the Midwest we have been bothered for a long time by the fact that we turn out about 32 percent of all of the Ph. D.'s in science and technology and yet we get nowhere that proportion of research grants, and I am sure many of the people we educate are promoting activities on the east and west coasts. In the Midwest, if I might speak to you as a compatriot here—although I am originally a New Yorker, I have lived most of my adult life in the Midwest—I think we hope we can create greater strength there since we have the educational strength, we hope we can have a greater proportion of the research in the total country. But I say this is an ideal, and I believe that the Science Foundation is uniquely set up to move toward this ideal from the present reality.

Mr. ROUSH. You would agree this is a goal that we should work toward?

Father HESBURGH. It is a goal. We are working toward this goal in several practical ways.

Mr. ROUSH. Is there a relationship between the geographical spread of institutional centers of excellence and the geographical distribution of the Federal research dollar?

Father HESBURGH. There should be I believe, and I would guess that if you look at some of the very interesting graphs that have been gotten out on NSF research money, we do them by sections of the country, and we show the production of Ph. D.'s and the percentage of research. I think you will find a fairly good correlation there. I took your question on the Federal dollar as not just NSF but the total Federal dollar, and this gets into NASA, DOD, and many other areas.

Mr. ROUSH. The National Science Foundation does very well, and I think it is commendable that they are working toward this goal.

However, the fact that you related just a moment ago that the Midwest, for example, produces 32 percent of the Ph. D.'s in science and engineering I believe casts doubt on whether or not there is a relationship between centers of excellence in the educational institutions and the geographical spread of the research dollar. Now, looking at this the other way, does the concentration of the Federal research dollar in certain areas of the country have a tendency to pull away from other areas of the country the centers of excellence or their personnel, and is there a danger that this would happen?

Father HESBURGH. Yes, this is always a danger. It seems to me that this country is large enough that we can have an organic growth of science and education in the country. The danger you mention is true I think and does happen on occasion. We often have trouble keeping a top physicist if all of the high-energy physics facilities are on the east and west coasts except the new one at Argonne National Laboratories. I think what NSF is doing, though, and this gives me great heart and I think it is one of the most promising things we are doing, you see following on the Seaborg report and the Gililland report, which pointed up instead of 20 centers of excellence for graduate training in science and research a country of this size ought to have 50, 80, or 100, we have set out deliberately to create these centers of excellence by our science development grants. What we are trying to do is to spot them right across this country, and I think if you look at the spread of grants that have already been given and those that are being considered, you will see that there is a wide geographical spread, that we are creating centers of excellence in every part of this country, and that the hope for the years to come is that these grants will not just spread the graduate student but will spread the research and the research support. But I must say loud and clear, because I think I owe it to my own commitment to excellence, that you don't build up a country by chopping the tops off the mountains and filling up all the valleys and coming up with an eveness or a levelness throughout the whole country. I think you keep the peaks and you support the peaks for what they do to inspire the whole country to aim at the excellence that these peaks have achieved, and you build up some more peaks. I am for building peaks rather than building levelness and filling in valleys.

Mr. ROUSH. I am, too, heartened by the work that is being done by the National Science Foundation in this regard.

Mr. Chairman, I would like to discuss an area in which some of my colleagues have been asking questions. I have a question or two that concerns the social sciences. You mention this on the beginning of page 5 of your testimony. First, let me ask you if history is a social science?

Father HESBURGH. You could get a lot of argument on that.

Mr. ROUSH. I always thought it was.

Father HESBURGH. There are some people who say it is and there are some who say it isn't. I have never really gotten deeply into the argument, but I say you can write it both ways nowadays. There are some historians that don't want to be social scientists and there are others who think they are.

Mr. ROUSH. The National Science Foundation must take the view that it is not a science?

Father HESBURGH. We don't take the view that it is not a science. We take the view that there are certain aspects of history such as the history of science which are enormously important for an understanding of the scientific endeavor in man's history, and we support projects in the history of science, not in history per se.

Mr. ROUSH. But you do support projects in political science?

Father HESBURGH. That is correct.

Mr. DAVIS. If the gentleman will yield—would archeology and anthropology be a form of history?

Father HESBURGH. Of course. In a sense for ancient history it is all you have for a real base, where there are no written documents, where you have to go on artifacts.

Mr. ROUSH. I had occasion to call the National Science Foundation yesterday relative to an inquiry received from a constituent who was interested in doing something that pertained to history. This was the answer I received, and I wanted to check with you to see that it was correct. I noticed a little conflict between your testimony and our report, "the National Science Foundation—A General Review of Its First 15 Years." You say that the National Science Foundation supports research in anthropology, economics, psychology, sociology, political science, geography, and linguistics. However, I note in this report under the support which is given to social sciences that we have only listed anthropology, economics, sociology, and history and philosophy of science at those areas having received grants since 1961. Now, are these which you have mentioned included in those which I have related as appearing in this document? Does NSF have grants in political science, for example?

Father HESBURGH. Yes.

Mr. ROUSH. And in linguistics?

Father HESBURGH. Yes. There are two ways of reading this. Our normal reports will mention under social science anthropological, economic, and sociological science, history and philosophy of science, and special projects. Most economic and sociological proposals are included under economic science; linguistics under anthropological and sociological depending on the particular project. Political science and social psychology are listed under sociological science. Some of these more recent additions to our program, such as, for example, political science, would not be represented as helpful as where we started in basic economics and sociology in the early days when we established the new division. You see, when the act was written there was not included a division of social science. Dr. Bronk, a good number of years ago, I hesitate to give the exact year because my memory may fail me on this, but a number of years ago, I would say about 6 years ago, Dr. Bronk, who was then Chairman of the Board, established a special Board committee to study what we should do in the area of social science. We established first an Office of Social Science Research and then a year or two following that we established by full Board consent a Division of Social Science Research, with a divisional committee and with a Director who is present here today, Dr. Howard Hines. As this Division grew in the normal organic fashion I mentioned regarding the whole growth of the Foundation, we gradually would add other subjects. The last subject to my knowledge that we added was political science.

Mr. ROUSH. Are you still chairman of this committee?

Father HESBURGH. No; this Board committee was disbanded when we reorganized our Board into three basic committees. But the fact was that during those years up to the time the division was established I was chairman.

Mr. ROUSH. Do you feel that enough of the Board's funds have been channeled into the science of social studies?

Father HESBURGH. We on the Board feel very frustrated at times because we can grant such a small proportion of the worthy grants that we have. In other words, if you take the total number of grants that we receive and given the criteria of quality that are put against them for judgment, there are a number of them that we would reject because we don't think they have sufficient quality. But on the other hand, of those that have quality we are only able to give a reasonably small proportion of them, generally we would be lucky if we could give half of the grants that are really worthy of being approved. Now in social science what we have tried to do, and again I think this reflects the philosophy of the Board in everything we have undertaken, we have tried not to just rush headlong into a new program, and when the Board approved the Division of Social Sciences, it began at a fairly low level around $2 million, as I recall. When we were first talking about it, we thought we would try to double that every year, and we have now reached about $10 million expenditure. Granting this is not a lot of money compared to our total budget, and granting that we could spend a lot more money because we are getting more requests every year, we have tried to have a controlled growth, if you will, and a growth based particularly on quality judgment, and the only fair thing I can tell you is that we have a lot more good grants than we have money to support them, and not only can we not give a certain proportion of those good grants that we have on hand every year, and they are growing every year, but we also cannot grant the amount of money requested to do the job.

Mr. ROUSH. I note that since 1962 the percentage of awards made as to the proposals made has gone down slightly in this particular area while in the area of the physical sciences it has gone up. Does this mean that we are going away from support in this area rather than maintaining a certain level?

Father HESBURGH. No; I would not say that. I think we are trying to maintain a level, but again you get certain fixed commitments in the physical science that don't exist in the social sciences. For example, if you are running a national laboratory for radio astronomy, for optical science, for oceanography, for Antarctic research, for Mohole, etc., these are pretty fixed commitments, and some of them are not even. For Mohole, for example, the budget will go up and it will drop down. The fact is in social science there is a very strong emphasis in graduate fellowships, because the key to growth in any science is the development of people who have doctoral studies in these sciences, who are qualified to go out and to be university professors or to work in other functions, and we are trying desperately to build up the highly developed core of social scientists in our country. So we have very heavy emphasis on graduate support in this area. The second thing is the normal grant in social science which will not have anywhere near

the dollar volume as the grant in physical science, because in social science there is not the emphasis on physical equipment that comes in the physical sciences. Often, it is a question of allowing a person to travel where he can study some ruins, if you will, or to travel where he can study some particular kind of social organization in a cultural anthropological study.

Mr. ROUSH. Wouldn't this mean in this particular area that more assistance and more attention could be given to the smaller college and university in the area of social sciences?

Father HESBURGH. It certainly could. And I think consonant with all of our other developments in the Foundation this is what we are trying to do over the long run. There are a great number, if you look at the current grants, for example, out of 770 research grants from the Division of Social Sciences activity, at the close of the year 1965, 690 of these were to colleges and universities, and if you break that down further, at the close of fiscal 1965, one or more social science grants were held by 335 different departments in 125 academic institutions, which is a fairly good spread for this Division given the fact that it is our latest created Division. I hope we can get more support for social science. I think it is enormously important. I think if you take a look at the history of social science support in this country you will find that when we created the Division we were really filling a vacuum because if you take the large foundations of this country, I am talking now of the private foundations, some of them have a history of getting into social science and then getting out, and when the very large ones get in, the smaller ones tend to get out feeling that the larger ones are going to carry the role. At the time we got to considering social science in the National Science Foundation, one of the large foundations had gotten very heavily involved in social science, even to the extent of erecting a national facility in social science, and then, having somewhat withdrawn, leaving a vacuum in this field. When the Science Foundation came into filling this vacuum for very legitimate reasons, since we had the authority in the act to do so, then we were in a sense swamped by these people who had very legitimate research needs and very legitimate study needs for graduate fellowships, and we were one of the few agencies who could fund these needs.

Mr. ROUSH. Mr. Chairman, I am sorry to take so much time. I would like to close with a comment of my own and to explain the reason for pursuing this. I know that one of the great national problems we have today is the problem of crime. In attempting to get some background on this problem, I have been amazed and somewhat shocked to find that there is very little research being done in the field of human behavior and in the sciences which are involved in the handling of our crime problem. I see in this a real potential for some agency of the Government and for various research centers of this country which might be capable of dealing with the problem. I am hopeful that sometime in the future it might receive some attention.

Thank you, Mr. Chairman.

Mr. DADDARIO. Mr. Mosher.

Mr. MOSHER. Mr. Chairman, it seems to me that Father Hesburgh's testimony concerning the Foundation has been very encouraging and most significantly so because of his long experience on the Board.

Personally, I want to say that I am very happy that with his special background and the point of view he represented that he has been on that Board. I only have one question.

Father, at some point in your testimony you suggested that some people had felt that the Board might be smaller. You personally testified to the efficiency of the way it has operated and its effectiveness. Do you want to go into that a little bit more thoroughly? If you had your druthers, would you run a smaller board or a larger board perhaps?

Father HESBURGH. Mr. Mosher, when I went on the Board in the first instance, I said how is it possible for 24 people to do business, because many of the boards I happened to be on at that time were smaller boards. But I soon found out on the National Science Board if someone hasn't something significant to say, he doesn't say anything. The group has a great cohesion, because many of the members are together for 6 to 12 years, depending on whether they are reappointed to the Board, and people look to different members of the Board for different points of view and different kinds of expertise that bear upon the subject under discussion. The Board has a very good committee structure. There is an enormous amount of time put on outside of Board meetings in committees. We have had a very capable staff. They have given us information in amplitude, by that, there is no stinginess about the paperwork there. We get everything we need and with a full look at it. So it is a rather unique board because it is this size, but I think its size brings it some of the spread of point of view and some of the spread of expertise that was questioned before, and it also gives it a very good geographical spread. In other words, we have every part of the country represented on this Board. We have a member of the State of Washington right now, to give you one extremity. We have almost always had members from the State of Texas. We have had members from the east coast, we have had members from the Midwest, we have had members from the South. Geographically it is a very fine spread and always has been, and as a result provided that the Board continues to operate with the Director and with with the same kind of relationship it has had in the past, I think it is a good size, and I think most of us felt when the question was raised of, say, cutting it down to 18 members or less, we felt this would be a mistake.

Mr. MOSHER. This must mean then that the various occupants of the White House, have been wisely concerned in selections to the Board?

Father HESBURGH. I would say so. I would think over the years there have been very few selections to the Board that the Board itself would not have selected if they had a complete choice in the matter. They were allowed to recommend.

Mr. MOSHER. Does the White House ask for the Board's recommendation?

Father HESBURGH. Yes. They always have in the past, and I would assume they would continue to do so. They also ask for recommendations from other large boards such as the American Council on Education.

Mr. MOSHER. Just one more question. Do you think the Board will look with favor on other projects like Mohole?

Father HESBURGH. I think there is a constant concern on the Board that there are large areas of science in which the country might be falling behind, and when we perceive such an area, be it oceanography or getting at the earth's crust, which is a very exciting project scientifically and something we know very little about at the moment, or atmospheric science, or this whole area I mentioned earlier of astronomy, or the wonderful research going on in the Antarctic, not just the research itself but the cooperation of so many nations in the project, we believe we should undertake these projects, but at the same time I think everyone on the Board feels a reluctance to get into a big project because a big project tends to cut into what we consider our main show, if you will, which is basic research in all the universities of the country.

Mr. MOSHER. It can distort your program?

Father HESBURGH. And the educational projects. We have generally had good understanding from the Congress on this, that with the addition of these large projects they have enlarged our budget so we don't completely distort the total program, but I think all of us feel at times we would like to have a little more free money for basic research and for some of our educational projects, and particularly we would like to get good support in the science development project, because this is institutional support for institutional growth in creating these centers of excellence on a much larger magnitude and geographic spread throughout the country.

Mr. MOSHER. Father, when there are large gaps that need to be filled, do you think the responsibility of the Foundation is to step in?

Father HESBURGH. I think it has to. It is the only one that can do this. When we made a study of astronomy, it was the Board's conclusion, after making a very complete study that went over several months, taking a lot of time of individual Board members and staff people, that there was really no other agency of the Government that could do this on an organic planned fashion so we weren't duplicating or overlapping but we were getting what this country would really need in a consistent program of land-based astronomy over the next 10 years. I think we have very little choice in this matter because there are areas which tend to slip behind and there are new areas that are coming into science that have to be supported and given the flexibility of the Foundation and the decision of its Board, it seems to me that the only answer is, and I see no way of avoiding this, that the Foundation budget will simply have to grow as it takes account of these other commitments, especially to see that they don't bite into our very basic commitment to education and basic research.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Mr. Chairman, Father Hesburgh, I first would like to state a few conclusions, that I have formed over the past few years, in order to make my question a little clearer. In the first place, I usually try to go annually to the Westinghouse Science Fair competition in which there are 50 contestants and they select the first-, second-, and third-place prizewinners. The first time or two I was more or less lackadaisical about it because I had assumed that every one of the contestants probably had a Ph. D. for a father and had been indoctrinated ever since he was in kindergarten. However, one night I happened to sit at a table with a boy who, as it turned out, had won the first prize.

I had a chance to talk to him a little about it, and I was astonished to find out that his father took no interest whatsoever in science; I think his father was a shoe salesman.

Two of the contestants, as I recall, came from the same science class in a Miami high school. This impressed me as to the value of a good teacher in a school system.

Second, I would like to mention the fact, as was brought out in testimony when Dr. Keppel testified before us the other day, that the different school districts in the United States are virtually autonomous. It couldn't be brought out any more graphically than it is being now in the Southeast with the implementation of the Civil Rights Act, where the school districts know that they are not going to get any form of Federal funds next year unless they comply with the Civil Rights Act. Dr. Keppel, for example, cannot pick up the telephone and call the State school superintendent of Georgia and find out anything because the State school superintendent cannot exercise power over the local school boards.

Father HESBURGH. There are 200 different districts in Georgia.

Mr. DAVIS. I would have guessed we had more. I represent 14 counties, and some of them have as many as 3 separate school districts.

Father HESBURGH. That is right.

Mr. DAVIS. So, as applied to a national program, we are dealing with a great many separate entities when it comes to trying to bolster the science program in a school.

Now, third, I do not want to take too much time discussing my own district, but it does happen to lie in Appalachia, and the living standards are somewhat below the rest of the country. I have always been very anxious to see the young people take advantage of such opportunities as might exist with the Government or anywhere else. Well, it turns out that we have virtually no applications for scholarships in the natural sciences from my particular district. Yet, that is the area of maximum help as far as the National Science Foundation is concerned.

As a final observation, I do not think there is any finer part of your program than the summer institutes program in which you update the teachers, and, also, the course improvement program. I wonder, however, if your Board has devoted any thought to the problem of providing some sort of incentive to the teachers to attend these institutes and to improve themselves. In other words, since there is no possibility, as I see it, of establishing a line of communication with every independent school board in the country, has the thought occurred to you to explore some way of providing an incentive on the part of the teachers to attend these institutes?

Father HESBURGH. We have, I think, tried to build in the incentive that it is more worthwhile for a teacher, say, to come to one of these institutes and get a reasonable summer salary for doing so than to have to run an ice truck or work in a grocery store, something of this sort. So the big incentive was first of all financial. The other incentive that we felt was important here is that most school districts—perhaps I shouldn't generalize—many school districts have a built-in incentive that with additional educational effort on the part of the individual teacher, the pay scale rises. I think this is a fairly universal phenomenon, at least in those school districts I am familiar with.

In all of this effort of equalizing opportunity today, we could find other means of getting at these teachers, that perhaps it never occurs to them that this possibility is there. I have a feeling—and it is no more than a feeling—that this is maybe a matter of communications. You see in all of the advanced school districts, I am sure every science teacher knows and knows far in advance that these are the possibilities. We allow a wide range of attendance at these so that a teacher, perhaps, in New York State could go out to Colorado, to the university there for a course, and this might do two things.

Mr. DAVIS. That I didn't realize.

Father HESBURGH. This could do two things. It gives the teacher a chance for a change of scenery, which I think they need every once in awhile, and, also, new science in a science department in which they can upgrade themselves. It would be possible for teachers in your State to go to some other State entirely—North, South, East, or West—and apply. I have an impression where you get a school district that is a little depressed because of the economic-social situation of the teachers, that it is just quite possible that the word doesn't get around as much as you would like it to, and I don't think this is for fault of publishing the word and trying to get it out, because I am sure we have used every possible mechanism to get this word out to all the teachers of the country, and all the professional societies for teachers have the word on this, but it is always possible to do a better job and maybe this is something we ought to give a little attention to. I would be very happy to take a look at it, and I will follow up on it.

Mr. DAVIS. I would appreciate it. Isn't it also quite likely that the prestige of being a teacher continues to grow?

Father HESBURGH. That is true.

Mr. DAVIS. In times past I know in my part of the country it was thought of as a job for a woman, and it was very poorly paid. Education was thought of as something you could more or less button up and say, "I am educated. I have finished learning."

Father HESBURGH. This day is gone forever.

Mr. DAVIS. I think, too, since this day is gone, as soon as that realization sinks into the public consciousness the prestige of being a teacher will increase considerably.

Father HESBURGH. I think the great thing is you find in the Foundation all of the mechanisms for getting at the very problem you mentioned, and I think that our only problem is to make sure we get a greater response, because I think, as I mentioned in my paper, about half of the teachers of the country have never applied to come to an institute. Some of them may have a family situation that makes this impossible. They may not be able to travel. They may not live near a university where they are teaching. But we have, I think, over the years given very wide support throughout all the universities in the South, and I think it wouldn't be necessary to travel too far. Although they could go to the North, South, East, or West, as I said, there is a great deal of mix. At our own university I have been surprised to find when I have talked to teachers that I have met some from the Atlanta district, coming up from the South, who have possibly come up for a change of scenery, perhaps.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. No questions.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have a few questions, but I think time is running short on us. You refer to the Director being appointed by, and responsible to, the President, and that the Director of the Foundation is a member of the Board. I also presume he is responsible to the Board. I am curious to know the relationship between being responsible to the President and being responsible to the Board.

Father HESBURGH. I have never sensed any problem here, Mr. Vivian, because the Board essentially makes the policy for the Foundation, and the Director over the years to my knowledge has tried to be sensitive to the policy indicated by the Board. Of course, he has a very difficult task in many ways because the staff of the Foundation grows and his problem is to project this policy to all of the members of his staff.

One other thing I haven't mentioned in the testimony, but it is just a practical working relationship, there are very few meetings of our Board that don't have present at them all of the divisional heads of the Foundation's various programs. We do have executive meetings, of course, from time to time, but the fact is that we think it is a very educative thing both for the Board and the staff to have almost an equal number of these members together to be privy to these discussions, because they are there giving us information that we are constantly asking for, and they are there to hear what the Board feels about their programs, the direction it is going, and the quality of it and so forth. So it becomes a little simpler for the director if his staff people are in the room hearing all of the discussions of the Board very periodically, and for them in turn to pass the word to the whole organization.

Mr. VIVIAN. Does Dr. Hornig appear at your Board meetings often?

Father HESBURGH. Only on special occasions. I would think over the years we have had the President's science adviser at the meetings any time we had a question concerning his office or a question in which he could speak to national policy in a broader sense than we could as Board members. There has been always a great cordiality here.

Mr. VIVIAN. How often have conflicts arisen between PSAC and OST?

Father HESBURGH. I would say once the Board knows really what it wants to do and is firm in what it wants to do, there hasn't been any insurmountable conflicts to my knowledge. My own reaction is they have been very helpful to us, these other groups of the Government. I think everyone is generally of the consensus that science and technology is very important in the total growth of the country, that we all have a role to play in this in our various responsibilities, and the real job is one of cooperation, of eliminating overlap, of working together on different levels, and this has been achieved quite well, I think. There are some people who think that science is overorganized, but I haven't seen any real evidence of it.

Mr. VIVIAN. You mention, for example, econometric studies, in which I am very interested. Would this bring you in conflict with the Bureau of the Budget? Would this conflict be resolved through the President's office or Dr. Hornig's office?

Father HESBURGH. No problem there that I know of. Since the very first days of our involvement in social science research, we have been involved in econometrics because it is a field so very closely allied

to the physical sciences. It is a very quantitative science, as you know, and it ties in with many other scientific endeavors. So far we have not had any reaction to my knowledge, any unfavorable reaction to our work in this field. I suppose we ought to be doing a lot more in it, but that is true in every field we are in.

Mr. DADDARIO. Father Hesburgh, I want to thank you on behalf of the committee for coming here today. I hope we might be able to send some additional questions to you.[1] There are many more to which we would like to have answers.

Father HESBURGH. I would be very happy to do that, Mr. Chairman. In any way at all I can help, you can call on me.

One point I would like to underline, if I might, in my testimony, and I think this is really the acid test. If there is going to be better education in the sciences and better basic research in the sciences, somehow all the universities in the country are going to have to be involved, and certainly because of the cost the Government and the Congress is going to have to be involved. My guess is that the nicest thing you can say about the National Science Foundation is that the universities like it, the universities feel at home working with it, they have felt in the collegiate slang of our day that there is very little Mickey Mouse that goes on between the university and the Science Foundation. There has been a great deal of trust that the university will behave themselves and be accountable in their activities. I think the universities' feeling toward the Foundation is a very real thing. It doesn't always exist, but it makes a very cordial situation in which Government and universities cooperate in something that is for the total good of the country.

I certainly think that the effort and time you gentlemen are putting on this is going to be very good for our Foundation because we are kind of very proud of it and we don't mind having it looked at. We all think it could be better. All of us who have had the opportunity to appear before you, have been extremely well impressed by the caliber of the questions and your general understanding of the problem.

Mr. DADDARIO. Thank you, Father Hesburgh.

Our next witness is Dr. Walter Orr Roberts, who is the Director of the National Center for Atmospheric Research.

We are not going to cut down on your time, Dr. Roberts. If for any reason we aren't able to finish today, we will make arrangements for you to continue at some other time. However, we might be able to work that out.

I am pleased to welcome you here. It is always a pleasure to have an Amherst man here.

STATEMENT OF DR. WALTER ORR ROBERTS, DIRECTOR, NATIONAL CENTER FOR ATMOSPHERIC RESEARCH

Dr. ROBERTS. Thank you, Mr. Daddario, members of the subcommittee. I am greatly honored to be able to appear here this morning in order to tell you a little bit about the work of the National Center for Atmospheric Research and to describe the unique partnership we enjoy with the National Science Foundation and with the universities of the Nation.

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

I would say that I have no objections in your breaking in and interrupting me, although since the time is a bit short and my testimony is a bit long, I will try to condense it as I go through.

A vast change is now occurring in our branch of science, which deals with weather, with influences on the earth's atmosphere from space, and with research on the atmospheres of the sun, stars, and other astronomical bodies. In the last 15 years or so, new opportunities have come into view—opportunities to acquire basic knowledge about the earth's atmosphere in which we live, and opportunities to put that new knowledge to use for the benefit of mankind.

Let me try to place in proper perspective the role that NSF has played in this development.

At the end of World War II, increasing numbers of scientists were beginning to consider meteorology as something more than the art of weather prediction. More and more they recognized that if we were to understand the atmosphere—for example, the factors controlling weather and climatic change, the genesis of jetstreams and hurricanes, or the mechanics of air pollution—we would have to do so in terms of the chemical, hydrodynamical, electrical, and other processes at work in the atmosphere. These processes would have to be defined in rigorous mathematical terms, and they would have to be understood as they occur in the atmosphere—interacting with many other processes occurring simultaneously.

For the first time, also just after the war, we began to develop tools commensurate with the scale of the problems of gathering the required data—high-altitude airplanes and balloons, rockets, and satellites, and new and more powerful devices, such as lasers, transistors, and thermistors, for measurement or analysis. In my view, the most important of all these new tools is the electronic computer. Without it, the many processes of the atmosphere, interwoven with fiendish complexity, could never be viewed as a unified system. And until this unified treatment is achieved, I expect progress to be slow in many areas of greatest practical importance. When the basic principles of the high-speed digital computer were first being realized and fully comprehended, at the Institute for Advanced Study in Princeton by John von Neumann and his associates in the lates 1940's, Dr. von Neumann predicted that computers would find their greatest scientific value in the study of the atmosphere. His words are at last beginning to come true.

The critical development, granting these essential new tools, has been the new concept of how to study the atmosphere. The word "interdisciplinary" has perhaps been overworked in science generally. But in the atmospheric sciences, its use is truly merited. Any process in the atmosphere—for example, ice formation in a cloud, or smog formation in a polluted urban area, or the birth of a great tornado-breeding storm system—is the result of many processes simultaneously at work, and they can't be separated out, but must be viewed together. The specialists in these processes normally work in different branches of science—with notable differences of method and subject. It takes a deliberate interdisciplinary push to bring them together.

If you wish to try to devise methods to predict, and perhaps to influence, events in the atmosphere—in order, hopefully, to bring more rain to a region, to reduce the danger of hail, or to dissipate a fog, or

to control air pollution—it is clear that you must launch a complex study involving physicists, chemists, engineers, and mathematicians with a wide variety of specializiations, and that they must form alliances and work together toward the goal.

In the first 10 years after World War II, individual researchers made considerable progress. But the pace was, and still is, too slow. Atmospheric research was woefully short of creative workers who had adequate basic science backgrounds. Educational efforts to produce the next generation of sophisticated researchers were lagging behind the need.

In addition, talented researchers in the universities were lacking facilities of sufficient scale and range to carry out their work. Therefore, a need existed for a new mechanism to serve as a focus for interdisciplinary work, to supply joint-use facilities, and to take an overview of where the science should be going—with the whole atmospheric science community participating. The National Center for Atmospheric Research was created as one significant thrust against this problem.

The next couple of paragraphs deal with the National Academy of Sciences' study issued in 1958 which really led to the formation of NCAR. That report made three recommendations, one of which was for the creation of a national institute for atmospheric research, closely linked to the universities. Dr. Thomas F. Malone of Travelers Insurance Co., was one of the people who participated intensively in that study and in fact in many ways is the "father" of NCAR.

In 1956, spreading concern about the gap between potential and performance in the atmospheric sciences led the National Academy of Sciences to conduct a special study, and out of this study came the idea for the National Center for Atmospheric Research. The Academy's Committee on Meteorology (now called the Committee on Atmospheric Sciences), under the leadership of Lloyd V. Berkner, issued a report in 1958 that stands as a significant milestone in the development of our national effort in the atmospheric sciences.

The National Academy of Sciences' report made three major recommendations. First, the scale of effort in atmospheric research in the universities should, as a priority scientific goal, be increased at once by 50 to 100 percent. Second, the American Meteorological Society should take on a major responsibility to stimulate interest in the atmospheric sciences, so that the Nation's youth might recognize the challenges and opportunities offered by a career in the atmospheric sciences. Third, a national institute for atmospheric research, intimately connected with the Nation's universities, should be established as promptly as possible.

The response to the third recommendation was the establishment of the National Center for Atmospheric Research (NCAR), in Boulder, Colo, in 1960. It is sponsored by the National Science Foundation, and its main financial support comes from a contract between NSF and our management corporation, the University Corp. for Atmospheric Research, or UCAR. We are an independent organization under university-monitored scientific management and direction. We have a broad charter to promote the growth of atmospheric research, in quality and scope, for the national good. The direction of NCAR is vested in me and in my four associate directors; we, in turn, must

not only be responsive to our national public obligations, but must also operate to the satisfaction of our council of members and the board of trustees. By appointment of this board I serve as director and principal officer of UCAR and also as director of NCAR, the scientific center and sole operation of UCAR today.

NCAR, though principally funded by NSF, does receive minor support from other agencies; and its management corporation, UCAR, has property, scientific equipment, and fellowships for graduate study financed by private contributions.

There were originally 13 universities in UCAR when it was established in 1959, and a 14th joined soon thereafter. In 1964, after the corporation had gained in experience, membership in the corporation was opened to any university that met certain graduate education criteria, the existence of a program of graduate study leading to the doctorate in the atmospheric sciences or a closely allied field. Today there are 21 universities in UCAR. Figure 1 shows their names and locations. The institutions span the length and breadth of our Nation from Hawaii to the east coast, from Alaska to Florida.

The UCAR board of trustees has legal responsibility and oversees management and general policy questions. A second body, the UCAR council of members, composed of a leading scientist from each member university, has principal responsibility for reviewing the scientific performance of NCAR, its services to the university community, and its overall goals. The council review procedure is a demanding and objective one involving a large range of scientific examination and justification. For example, I brought along the review document which we have just prepared for the review committee of the council, and this will be a matter of discussion and debate over the entire coming year.

Mr. DADDARIO. Dr. Roberts, is it true that the council's review procedure that you are referring to as being university-controlled, is in fact managed by members of the universities?

Dr. ROBERTS. The universities are the members. In other words, the universities serve as members of the corporation, and the universities appoint representatives; for example, the members of the board of trustees and the members of the council are officially appointed by the university and not by the board itself.

Mr. DADDARIO. They do not necessarily represent either the academic community or their own university, but they are university-connected people who are specifically involved in atmospheric research and deal closely with you?

Dr. ROBERTS. That is correct, sir. Yes. They represent broad national interests, and not the narrower interests of the individual universities.

The existence of UCAR has helped insure close communication within the university community. But I should emphasize that the facilities and visitor programs of NCAR—following up your point—like those of the other NSF-sponsored national research centers—are open to all scientists, from member universities and nonmember universities, from other private nonprofit research laboratories and from Government laboratories, from this country and abroad. The facilities of NCAR have already served scientists from more than 25 institutions; and during the past year we have had visitors for 2

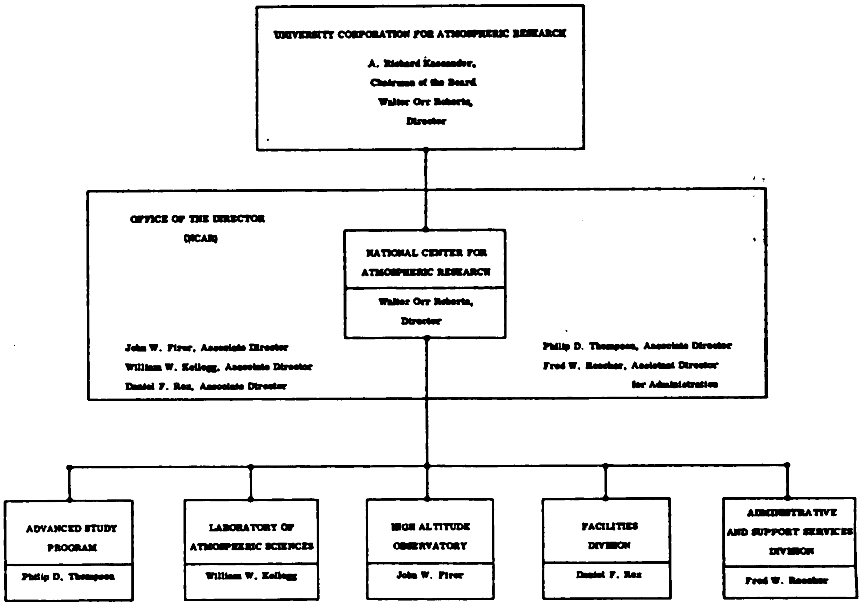
months or more from 35 institutions in this country and approximately 20 countries abroad.

NCAR today has a total staff of approximately 380, and we consider that in size, we are about two-thirds mature. Figure 2 shows a skeleton organizational chart.

Figure 2

ORGANIZATION CHART

THE NATIONAL CENTER FOR ATMOSPHERIC RESEARCH



UNIVERSITY CORPORATION FOR ATMOSPHERIC RESEARCH

We conduct basic research of an unclassified nature relevant to a number of areas of highest public concern. These include the cause, prediction, and possible control of weather changes, on all time scales from a few hours to long-term climatic changes; the prediction and control of the upper atmosphere and near space environment; the causes and cure of air contamination on a large scale, etc. We are not an applied research laboratory, but our scientists are deeply concerned that their basic results find prompt application to public use. One might say that our research program is need oriented, even though the payoff may take years to reach.

Speaking a bit to the question you asked Father Hesburgh about motivation to teach, I might say our scientific group, even though we have no teaching responsibility in NCAR, has very strong motivation to teach, and we have worked out arrangements whereby members of our staff can serve as affiliate professors in any university or college in the country, and some of our people have already availed themselves of this opportunity to go and teach for various lengths of time in different universities.

The basic research of NCAR is carried out not only by our resident staff, but also by a sizeable number of visitors, mainly from universities in this country and abroad. Our role, as we see it, is not only to carry out research, but also to stimulate research efforts in the universities on the most critical major problems. Many problems are so complex that only by enlisting the key scientists, wherever they are located, can we mount a suitable attack. This we do through working conferences to examine the current state of knowledge on critical problems, and decide what the next steps should be. This among other measures.

In addition, we have assumed a major responsibility to join forces with the university community in planning and making available large-scale joint-use research facilities not otherwise available.

Perhaps the best way to describe the current status of NCAR is to describe the work in each division.

The laboratory of atmospheric sciences is headed by Dr. William W. Kellogg, who, incidentally, was one of the first people to suggest the development of a weather satellite and worked out many of the details as to what it ought to be. In the laboratory of atmospheric sciences, which is one of two operating research laboratories at NCAR, we have some 35 scientists at the Ph. D. level who work on individual problems and in special project groups—often including visitors from the universities and elsewhere—in three principal fields: atmospheric dynamics, cloud physics, and atmospheric chemistry.

Atmospheric dynamics covers a lot of territory, of course, ranging from the motions of global wind systems to the nature of turbulent eddies that transfer energy between the ground or ocean surface into the first few inches of the atmosphere. A major NCAR effort is underway in the area of dynamics to design a new mathematical model of the atmosphere, building on the experience of dynamicists at UCLA, MIT, the U.S. Weather Bureau, and elsewhere, and carefully planned to supplement but not duplicate their work. From our study and from work in process in the universities and elsewhere, we hope that reliable mathematical models of the atmosphere will eventually be developed which can be used to simulate the atmosphere with enough realism to allow us to experiment in methods of long-range weather prediction and large-scale weather modification.

The next few paragraphs generally describe our research in cloud physics and atmospheric chemistry. Cloud physics is helping us understand the complex nature of the dynamics of the clouds and the rainfall process from clouds, and our ignorance of this subject may have been one of the reasons why cloud seeding has been such a disappointment for many years. I would like to say that atmospheric scientists have found some fascinating things, one of which, for example, tells how one of the old Southwest Indian legends seems to have had some basis; namely, the Indian legend that "droughts promote drought." If I get into that, it would take another hour. It is a most fascinating business.

Mr. DADDARIO. You shouldn't leave us hanging there.

Dr. ROBERTS. In a very brief, brief statement, one of the reasons that clouds over a continental mass don't precipitate easily is because the water droplets are too small and when they collide they bounce off

instead of coalescing. It appears when a drought occurs the soil becomes more favorable to sending into the atmosphere the very particles that cause excessive numbers of droplets to be very, very small, so that when the ground is dry and the sunlight beats down on it, it produces the very conditions that make it unlikely for a given cloud, when it forms, to rain. That, briefly, is the fascinating story.

I point out in my written text, in connection with atmospheric chemistry, that man may already be unwittingly changing the atmosphere, possibly changing it irreversibly by the injection of the jet airplane combustion products into the atmosphere and by other accidental means. If this is so, the implications of this unwitting weather modification may be a problem even more serious than the problem of air pollution, which, of course, is an area in which we also have a deep interest. In each of these cases, basic research is the essential key to information required to deal with these problems.

Cloud physics is, I believe, a widely known term today. It deals mainly with the formation of clouds and the complex manner in which small droplets condense and then coalesce into large enough drops to fall out of the cloud. It is a fascinating area. The production, for example, of rain from a shower or thunderstorm cloud appears to be a very complex mechanism; and our ignorance of the structure and dynamics of clouds is one reason why the hit-or-miss approach to cloud seeding, which caused so much anguish in the 1950's and early 1960's, has failed to live up to expectations.

In the field of atmospheric chemistry, we want to understand the life cycles of trace gases and solids in the atmosphere—carbon dioxide, ozone, etc.—and of the many kinds of particles, technically classed as "aerosols," that float about in the atmosphere—minute drops of resin from evergreen forests, petrochemical solids from auto exhausts, particles from plowed fields, meteor dust from space, etc. NCAR has a large effort in this area, which is really broader than the label of atmospheric chemistry.

We have concentrated effort here not only because it is a largely neglected and underdeveloped field, but also because a critical question lurks here, and it demands a prompt answer. It is possible that man is already modifying his atmosphere significantly, possibly even irreversibly, without even attempting to do so. For example, our burning large amounts of fossil fuel, or our injection of jet airplane exhausts into global air circulation, or the reduction of miles of farmland, prairie, and forest to urban development—these and other acts of man may conceivably be significantly altering our atmospheric environment already, and may even be affecting general weather patterns. We do not know if this is so, but we should find out. If it is so, it is a problem far more grave than the problem of air pollution, in which we also have a great interest and concern.

It is possible that some of the processes involved—such as the injection of carbon dioxide into the atmosphere—may even have century-scale effects on climate. To put it bluntly, we ought to know what we're doing, and the first step toward full understanding is accelerated basic research in the chemistry and physics of atmospheric trace gases and solids—a major aim of this division.

The second laboratory of NCAR is directed by Dr. John W. Firor, a cosmic ray and solar physicist. In the high altitude observatory

we study atmospheres everywhere—in the sun and stars, on other planets, in the space joining the sun and earth. We look at possible extraterrestrial influences on the atmosphere of the earth such as meteor dust, cosmic rays, plasma jets, and the solar wind. There has been, over the past decade or two, much speculation about extraterrestrial influences on the weather, especially in relation to connection between storms on the sun and storms on the earth. In fact, this has been my own personal field of research. This is research of the most basic type, yet it may eventually hold important clues about long-term variations in the earth's climate and the more abrupt changes in week-to-week and month-to-month weather patterns. It may explain things such as the spectacular reversal of climate in 550 B.C., or the change like the one in 1562 which caused a worsening of climate in England. I must say I find it difficult to restrain my enthusiasm in talking about this.

I am especially proud of the high altitude observatory's contribution. The observatory joined in our objectives in 1960, as I did, and we threw all of our resources and interests into NCAR's aims after a 20-year history (the observatory's and mine) of space-oriented solar and solar-terrestrial research.

NCAR's research activities benefit greatly from the participation and criticism of visitors. Over the earlier years of HAO's history we had formal reviews of our research performance by distinguished outside scientists. The UCAR council of members has now taken up the responsibility of formal review, under a plan designed to extend and amplify our earlier procedures. Under the new council plan, one-third of NCAR's future research projection will be reviewed in depth each year, according to a procedure quite similar to the anonymous-reviewer system used so successfully over the years by NSF and others. I have favored this review procedure as a further means of assuring vigorous and independent criticism of NCAR, and yet without courting the dangers of excessive or oppressive bureaucratic control of our operations or our goals.

The advanced study program is headed by Dr. Philip D. Thompson, a mathematician and one of the world's leading experts in numerical weather forecasting. This program has postdoctoral study activities and advanced seminars in looking at what the various roadblocks are in the various fields of research.

The advanced study program is the NCAR effort most closely linked to education. NCAR does not, of course, conduct formal course work, or grant degrees. But we do provide postdoctoral appointments for a limited number of new Ph. D.'s in the atmospheric sciences, astronomy, physics, geology, chemistry, engineering, aerodynamics, mathematics, etc. Under this plan we encourage new scientists to initiate their research careers in a place where they will be exposed to a wide variety of specialties, and where debate flows constantly about which scientific problems are the most important to the progress of the science as a whole. We conduct series of seminars on critical problems for the resident and visiting staff; and UCAR, through private funds, has a fellowship program for pre-Ph. D. graduate students who are free to study in any accredited university of their choice.

Let me turn to the Facilities Division, headed by Dr. Daniel F. Rex, who is one of the scientists who worked under the distinguished Carl

Gustav Rossby, who was an atmospheric science pioneer, and the great creator of two major atmospheric science efforts in the United States.

From the outset of planning of NCAR, the provision of facilities has been one of our prime activities. It is clear that balloons, airplanes, rockets, and computers are essential in atmospheric research; it is equally clear that many of these tools are beyond the reach of the individual university researcher and even beyond the reach of his university.

NCAR now operates three facilities for the joint use of the atmospheric community—in scientific balloon operations, in research aircraft, and in computer usage. We also provide expert consulting service to university experimentalists on experimental techniques, how to get access to existing capabilities elsewhere, etc. In fact, we view this "middleman" function as equally important with the provision of actual physical facilities themselves. Our balloon facility has helped to make advanced and difficult balloon technology readily available to university scientists. This is done through development work on balloon design, launching methods, and communication systems; and through the operation of two balloon flight stations, one in Texas and one in Arizona, where more than 100 flights are launched each year for scientists from more than a score of universities and other research groups.

Our aviation facility now operates two aircraft, and plans to carry out seven experimental projects this summer, four for NCAR staff members and three for outside scientists. The NCAR computing facility is also serving a variety of outside users who require a very high speed computer and experience in its use for atmospheric problems. This is particularly important to some of the smaller institutions that don't have major computer facilities.

Before proposing to the NSF that we undertake establishing any joint-use facility, groups of non-NCAR scientists have made thorough studies to determine whether or not the proposed facility is really needed, and to make recommendations as to how (and possibly by whom) it should be developed. Only when such an outside group has made an urgent recommendation that it should be done at NCAR, and when the NCAR staff studies also show that establishment of the facility is feasible and that no other agency or institution is in an equally good a position to fill the need—only then does NCAR move to create the facility. This kind of caution is essential. Funds for atmospheric research will always be limited, and must be spent wisely and sparingly. In shaping our facilities, we therefore are forever mindful of exactly what needs we should strive to fill.

The next few paragraphs give examples of some of the NCAR facility aid to various universities and how we have organized this, pointing out in some instances we have recommended the creation of facilities which other institutions have carried on, like the University of Hawaii.

For example, in our aviation facility, we have recognized that a university researcher can usually rent a light plane when he needs it. We also recognize that very heavyload, high-performance aircraft are operated for atmospheric research by the Weather Bureau and by the Air Force Cambridge Research Laboratories. NCAR's effort, therefore, is to supply flight time in airplanes that fall between these two

classes. We can thus provide the university researcher a capability he cannot provide for himself, but in aircraft that are smaller and far less costly to operate than the high-performance planes operated by various Government agencies.

With respect to facilities, we have also played a catalytic role. For example, cloud physicists and atmospheric chemists have long looked upon the Island of Hawaii as a near-ideal laboratory for probing the processes of precipitation. As the result of many discussions including several organized under NCAR sponsorship, the Institute of Geophysics of the University of Hawaii is taking the lead in developing such a facility. NCAR is assisting in obtaining, modifying, and installing radars, portable laboratories, power supplies, and communications equipment. But administration, scientific control, and planning responsibility will rest with the University of Hawaii. In short, the university is building and operating a research laboratory of broad national and international significance, and we are helping in this goal. This summer the Hawaii research site is in use by scientists from the United States and from Japan in a program sponsored by NSF and the State Department.

It is assumed, and I think rightly, that the proper site for the heart of the country's basic research is in the universities. This is true in the atmospheric sciences, as elsewhere. In addition, in the atmospheric sciences we have a special need to train a far larger next generation in a field that at times falls down the cracks between conventionally organized departments of a university.

It is also assumed here in America that university scientists can and will wisely do the bulk of the priority setting, at least within a given field of science. NCAR's relationship with the NSF reflects this basic NSF-university philosophy. We in NCAR are, of course, subject to all of the usual difficulties of the Federal budget's cycle. We often wind up with less support in a given fiscal year than I think appropriate for the science to which recent administrations have given such high priority. The problem is acute not only for NCAR, but for the whole of the atmospheric sciences. In time this problem of the need to expand a larger percentage of our total resources will become more serious because NCAR's goal, shared with NSF, is to promote a major advance in this rather neglected broad field of atmospheric science. If we in NCAR and the universities succeed, NSF will have far stronger and far more numerous atmospheric science proposals coming in from the universities.

Because our expenditures under our contract with NSF are subject to various Government restrictions and regulations, we have sometimes encountered snags that have caused serious delays or made it extremely difficult to carry on activities that both NSF and we consider integral to our aims and purposes, and much is in the public interest. NSF has given us solid support in helping overcome these obstacles.

Moreover, the Foundation has exercised its wisdom in this relationship in a much more important way. Both under Dr. Waterman and now under Dr. Haworth, the initiative in scientific planning and in facility development has been left to NCAR, in consultation with the university community. It has been clear from the outset that NCAR is, and should be, a private laboratory operated by a nonprofit corporation representing the scientific community. NSF's leadership

has been constantly vigilant in helping us preserve this principle. The terms of our contract with NSF are extremely broad—

> to organize, operate and maintain a center which will have the following functions of a scientific, interdisciplinary character—to plan and execute basic research programs in collaboration with other scientific and educational institutions * * *; to plan and execute basic research programs of small scale * * *; to develop overall plans for a permanent establishment * * *

(namely, the laboratory that we are now building in Colorado)

> and to carry out such other activities as are recommended from time to time by the Foundation or the contractor and mutually agreed upon by the parties.

This description of our task, it seems to me, is as close to a charter of scientific freedom as one could arrive at within sound governmental practice.

An essential justification for large-scale public support of atmospheric research is the prospect of practical benefit through application—for example, in control of air pollution, in improved long-range weather predictions, in a better understanding of the near-space environment, and in possible modification of weather and climate. Nearly every scientist, of course, wishes to see his research results useful to mankind. Moreover, we are aware that the NSF has been given explicit responsibilities in the field of weather modification.

Our concern with possible applications of knowledge, therefore, arises from both our own scientific interest and from the statutory interest of our partner, the National Science Foundation.

It is, however, characteristic of the atmospheric sciences at this point in time that the line between basic and applied research is impossible to draw. Indeed, there is a significant area of overlap. For example, the problem of constructing a mathematical model of the terrestrial atmosphere, the problem of developing long-range prediction methods, and the problem of realistically assessing various proposed weather modification schemes—all these problems are essentially the same now. But we can see the time not far off when they will begin to diverge, and the question then arises, what should NCAR's role be?

This example of overlapping practical and theoretical problems is particularly relevant because of the imminent development of a global observing network over the next several years.

Dr. Hollomon described briefly, when he was here last week, a most challenging example that has far-reaching potential benefit to the country. In order to make further progress toward understanding the global weather circulation, or to discover how far in advance it is possible to make weather predictions, or to examine the feasibility of various methods of possible weather and climate modification, the network he described must be initiated and operated for an experimental period. We now receive adequate data from only 10 percent of the earth's surface. Ninety percent of the globe is inadequately covered. Satellites, combined with constant-level balloons, ocean buoys, and land stations, offer for the first time a scientifically and economically feasible way of getting the data we need for research progress on the above questions. The experiment will also constitute a very exciting feasibility test of a possible means for an ultimate international weather observing system.

The test will show how much these data can contribute to improving weather prediction using current methods, and more importantly, will spur more rapid development of better prediction methods. They will also contribute to the investigation of a broader question—how predictable the atmosphere really is—that is, how far in advance prediction can ultimately be pushed, and with what accuracy.

Dr. Jule Charney of MIT recently led a National Academy of Sciences study of the potentialities of adequate global observations. In this he foresees a real prospect for 2-week forecasts with an accuracy as good or better than our current 3-day forecasts.

NCAR's interest in the global data concentrates principally on using them for simulation tests of potential weather and climate modification schemes. Before large-scale weather modification schemes are tried in nature, it is essential that global data, taken from the real atmosphere, be used in a computer of adequate size, to discover the full effect of each scheme. For example, we must know whether an effort to relieve a Great Plains drought might not also freeze oranges in Florida. It would be an irresponsible and reckless act to try such schemes in nature without exhaustive prior simulation tests leading to a very high level of assurance of safety, in spite of the potential and extraordinary benefits that would result if the operation could be safely done. Weather modification schemes of this sort, if they work at all, are moreover likely to be realistically computer simulated if global weather data of the type that Dr. Hollomon spoke of become available.

Organizing and setting up the experimental global observing network, is, of course, an enormous administrative and engineering task, requiring complex cooperation on both a national and international scale. Clearly, its management belongs in agencies with existing operational capabilities and responsibilities. It seems to me that the logical agency in this country to manage it is the U.S. Weather Bureau, now in the Environmental Science Service Administration, whose leader Dr. Robert M. White is an outstanding atmospheric scientist. It is not within the current NCAR concept to play the major management or operational role in such a large venture, even though we will soon launch—or hopefully soon launch if some of the difficulties connected with it of an international nature can be cleared up—in cooperation with the Weather Bureau and the Government of New Zealand, about 100 balloons designed to circle the world repeatedly, staying up for 6 months or more, following the natural wind circulation, and transmitting data on winds, temperature, humidity, etc., by means of an extremely light-weight electronics package. I am going to demonstrate it this afternoon, so I brought along the radio transmitter. This fragile device will transmit weather data 3,000 miles to ground stations from a balloon, which is hopefully to fly for 6 months. The radio will be powered by solar energy.

We are also interested in participating in the design of a supercomputer adequate to process the vast amount of data from the global network for large-scale research weather modeling purposes. The computer will have to be about 100 times more powerful than any existing computer. NCAR stands ready to mobilize a team of mathematicians and dynamicists to help write the scientific specifications for such a computer.

51-204—65—vol. 1——33

When the computer is developed, it will be an essential tool in testing global weather modification schemes such as I have mentioned, and it will be our aim in NCAR to own and operate such a computer in order to do so, by numerical simulation, realistic large-scale weather modification, such as jet stream deflection, drought modification, hurricane steering, etc. Such experiments will have great significance also in long-range weather forecasting research—since prediction and modification experiments are part and parcel of the same scientific problem as long-range forecasting. But we do contemplate manning a computer for operational purposes.

We do stand ready, however, to assist in any task connected with the global observing network for which we possess special qualifications. For example, it is likely that certain scientific recommendations may be called for from working groups of university scientists. Because of our close relationship with the universities, NCAR might well be the logical sponsor and host for such groups.

There are other, more modest but still sizable, efforts in atmospheric modification that may yield important practical benefits in years to come—connected with hail suppression, fog dispersal, amelioration of air pollution, modification of the radio reflecting ionosphere, artificial aurora production, etc.

In such areas, NCAR's role will be concerned with the linkage between the new knowledge now being produced and its wise and prompt application. Our role will be both analytic and catalytic. We will examine progress being made toward applications; help assess the potential value of such applications; define major scientific and technical roadblocks and knowledge gaps; and assist in planning specific attacks aimed at clearing the obstacles away.

In seeking to plan ways to couple basic research results to practical use, we in NCAR will call not only on our own staff, but on atmospheric scientists from the universities and elsewhere to join us in special studies lasting from several months to over 2 years, each study devoted to a specific problem for which we have staff interest and competence. If it should develop from such analyses from time to time that NCAR is the most logical group to carry forward a major experimental program—for example, in the investigation of hail suppression methods—we will do so, but only if we have full endorsement and cooperation of the agencies who will ultimately be responsible for the application.

By organizing and limiting our effort in this way, it is our expectation that we can avoid losing the essential focus of basic research we have now attained, and still make a unique contribution toward the achievement of wise and effective applications. And this mode of activity, I believe, will put us in highly effective partnership with the scientific community and with various interested Government agencies.

In conclusion, Mr. Chairman, I would only say that from my view the Foundation's leadership and support of our effort have been bold and effective. The partnership I have described has been more successful than we dared hope at the outset 5 years ago. Five years ago I felt that hope was shining enough to be willing to change my entire field of scientific research from astronomy to atmospheric sciences, and the rewards have been enormous—the association with the highly

competent staff of the Foundation in atmospheric sciences and the support and enthusiasm of both Dr. Waterman and Dr. Haworth. It has been an evolving partnership, not without problems and obstacles; but it has, I believe, proven its soundness and usefulness to the society and the scientific community it serves. I believe that a study of the other two NSF-sponsored national laboratories would reveal a similarly effective accommodation to the needs of the American pattern for building a stronger science for public good.

Thank you, sir.

Mr. DADDARIO. Thank you, Dr. Roberts. Mr. Davis.

Mr. DAVIS. I recall 2 or 3 years ago Dr. Edward Teller showed a film to our committee. It was a display of a week's worth of weather. As I recall it, it showed the movement of isobars around the earth's surface. Was that effort in any way coordinated with NCAR? Where was he working from? I don't recall.

Dr. ROBERTS. That film that you speak of, sir, was I believe prepared by Dr. Cecil Leith, of the University of California, at the Livermore Laboratories and was one of the first applications of a major computer to the preparation of an actual moving picture map of weather systems. It was very striking in the reality that it showed, even though the model was enormously simplified. That was done before NCAR had a major research capability in this area, but Dr. Leith is now chairman of the computer advisory committee of NCAR and is the man principally taking the lead in advising and helping NCAR to develop computer capabilities to extend this sort of study to a far more realistic model. Leith's model, in spite of its fascinating similarities, to real weather, had many features that were unrealistically simple. But it showed such promise that we believed it could be done realistically if we have the resources.

Mr. DAVIS. I recall they did not program the Rocky Mountains into that.

Dr. ROBERTS. That is correct, sir. The Rocky Mountains, of course, have an enormous influence on the weather all over the world. They stabilize a position in the average trough systems so that the Rocky Mountains influence the weather not only of the United States but the weather of England and the weather of the whole Northern Hemisphere. We are quite proud of those Rocky Mountains of Colorado!

Mr. DAVIS. I don't blame you a bit. What incentives are there for a university to become a member of NCAR and what expense would be entailed?

Dr. ROBERTS. We feel that the principal incentive to a university is an opportunity to participate in the planning, guidance and management of something designed to change the whole science in the public interest. A university, to become a member, has to agree to provide a scientist, or two scientists and an administrator if it is one of founding members of NCAR. The original 14 founding institutions had to make contributions of cash, and I regret to say I forget the exact amount. (Added later: $2,500 was required of founding members.) The new institutions brought in now have to make a nominal contribution of cash (added later: $1,000) as a token of membership. They also have to meet certain criteria, certain standards in respect to the offering of graduate courses of instruction and research leading to the doctorate in atmospheric sciences or a closely related field.

Mr. DAVIS. You said they have to provide a scientist. Does that mean they have to provide a person to reside at NCAR?

Dr. ROBERTS. No, sir. They must name a representative to serve on the Council, and if they are one of the original founding institutions, they must in addition name two trustees, one an administrator and one a scientist. The Board of Trustees handles management, fiscal and budgetary policy, and the Council of members handles scientific guidance, evaluation and so on. The institutions designate a person to serve on this Board when required, and many of these men, like Dr. Robert Fleagle, of the University of Washington in Seattle, will spend probably 20 days over the coming year, maybe even longer, evaluating the performance of NCAR, seeking reviews of its competence, developing constructive criticism and so on.

Mr. DAVIS. Do you consult or are you in communication with such agencies as the FAA as to what their requirements are? What they would really like to know, for example, about thunderstorm activity and things of that kind, and where they need help? Do you communicate with agencies like that?

Dr. ROBERTS. Yes, sir. We are in quite close touch with agencies, many agencies. Nearly every agency has some involvement in weather science, and we are in touch as widely as possible, where we feel that one of the new discoveries or one of the areas of promise in basic research may have an ultimate or even a short-term application to the interests of the particular agency. Our scientists have a sort of responsibility as a member of a national laboratory to make themselves available for advice to government, to industry, to the universities, to anyone, that has a legitimate and proper scientific need for this information, to consult about where application might be made. I might say that the scientists regard this responsibility as a very important and serious one.

Mr. DAVIS. Dr. Hollomon the other day made an observation to the effect that the people who generally—I am not sure I am going to quote him exactly right—generated and funded the research, are usually favored with the fruits of research. With that particular thought in mind, what has generated the interest in NCAR in these universities which you show on the map? Can you put your finger on agriculture or any particular thing?

Dr. ROBERTS. No.

Mr. DAVIS. Is it just an esoteric interest in meteorology?

Dr. ROBERTS. The basic interest which led to the creation of NCAR and the participation by the universities was the realization that the atmospheric sciences had not kept pace with the progress of chemistry, physics, and other areas of science in spite of the development of relevant tools. So it was essentially realizing that the short-term demands for application should not be allowed to stand in the way of bringing this science to the most modern peak of excellence and contribution as a basic research activity.

Mr. DAVIS. Is the interest one that stems from simply intellectual curiosity or is there a practical need? For example, the depression brought on a need to study economics. I notice the distribution here doesn't seem to follow any particular pattern. Would you say it is simply an intellectual realization of the truth?

Dr. ROBERTS. Yes, sir, I think so. It was a realization that this science generally has an enormous contribution to make to the welfare of the country, and that the universities should, as a matter of responsibility, join in bringing it up to a modern state of excellence. This, in fact, was the essence of the National Academy of Science's report, that third recommendation I referred to earlier. The recommendation was that without the creation of a major basic research center like this, the science would continue to lag, partly because of the extraordinary demands that were made for the training of relatively nonscientific weather observers for the weather service. This generally in university structures led the Department of Meteorology to be looked down upon by bright young mathematically and physically oriented students who were considering a scientific career, because "over there" is where you drew isobars and weather maps and wet your finger and held it up in the air; and that wasn't for them. It was felt necessary that to make more evident the real challenge, for this scientific problem is one of the most difficult scientific problems ever undertaken by men. It was felt necessary for it to have a chance to contest with physics and chemistry and other "nonessential" sciences—excuse me, I shouldn't have said that—to contest with the other sciences for the talent of the most outstanding youngsters. That is the heart of the problem. We need to get the first rate youngsters to be interested in the atmospheric sciences, not those that just can't take math. The math and the engineering that are involved in the atmospheric sciences are among the toughest problems. The problems are equal to the toughest in nuclear physics or molecular biology. I personally believe the potential benefits to our society are equal to nuclear physics or molecular biology.

Mr. DAVIS. I notice in the paper this morning that the Weather Bureau is a nonprofit organization. The hooker was they spelled it p-r-o-p-h-e-t.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Do we have your budget figures over the last few years? I assume we do.

Dr. ROBERTS. If you don't, we can provide it.

Mr. CONABLE. Do you have any budgetary comments?

Dr. ROBERTS. No, except the Foundation has been giving us very excellent support. We have had long and detailed discussions of the objectives and the needs, and they have given us solid and effective support in achieving the objective.

Mr. CONABLE. Has your budget risen faster than the overall budget of the Foundation percentagewise?

Dr. ROBERTS. It is certain to have, sir, because we had no budget before 1960. But it has risen quite abruptly.

Mr. CONABLE. In the last 2 or 3 years?

Dr. ROBERTS. Yes. It was considered a necessary objective because of the particular requirements of atmospheric science that a major laboratory be created as rapidly as it could be created.

Mr. CONABLE. And you expect that will continue until you reach the maturity that you say is now only two-thirds in all probability?

Dr. ROBERTS. Yes, sir. Although the curve of funding and the curve of staffing has already begun to level off toward the objective which I very firmly hold in mind of a limitation of growth at a size of about

600 scientists as compared to about the 380 or 400 that we now have. After that the growth will be "sub-Parkinsonian."

Mr. DADDARIO. Mr. Conable refers to the fact that you have budget problems on occasion. I imagine this is one of the things that goes with this charter of scientific freedom that you have arrived at.

Dr. ROBERTS. Yes, sir.

Mr. DADDARIO. You wrestle with that as the rest of us do. Do you have some thoughts about the development of such an organization as yours, of others of its size and rigidity, and then the maintenance of continuity are a part of the National Science Foundation, current and future function? How do you look at that as being a proper function within the National Science Foundation? What effect might it have on the other work which the National Science Foundation might have to do? Father Hesburgh touched on the fact that certain of these inflexible parts restrict the opportunity to do more things in other areas. Now does this fit in, in your view, Dr. Roberts?

Dr. ROBERTS. Of course, I have never been privileged to be a member of the National Science Board or to sit in on their deliberations, but from where I sit the case of a science that is severely underdeveloped compared to its potential contribution, it seems to me, following again the National Academy of Science's argument, it seems to me there is no other way than to create major facilities or major research capabilities aimed at basic research, not aimed at a particular mission orientation. You see, in the atmospheric sciences particularly, the short term demands of the particular mission—orientation of the agency, like the Weather Bureau, for example, make it difficult for research to grow in an appropriate pattern. I think it is a fairly established thing that in the Weather Bureau basic research did not prosper as the potentialities represented by physics, mathematics, computer science, etc., made potentially possible. It was the conclusion that an activity closely related to basic research in the university community was necessary. That being so, that the National Science Foundation was the logical and proper agency under which for this to develop. I think the crux of the matter of whether it is proper and going to be effective in the long run, the crux of the matter depends on whether the institution, NCAR (or the other national laboratories), continue to serve the basic research needs and continue to benefit the universities of the country generally. If, for example, NCAR should get its eye principally on doing research in the fastest and most effective way and not on the growth of the university community and the atmospheric sciences in general, than I think there would be some hazard in the NSF funding of the laboratory, but I can assure you as long as I am Director of NCAR it will exist to serve the universities and progress in basic science.

Mr. DADDARIO. The guidelines you spell out involve the development of programs in basic areas with a great requirement being on the need and the effect it will have on the Nation and the fact that we can fund that and still do the other things which must be done?

Dr. ROBERTS. Yes, sir.

Mr. DADDARIO. This would mean then that there should be serious and important debate on each of these programs so that the Congress would recognize that this is being done, therefore, they cannot pick

that up, and support the rest of the program in a proper percentage relationship to what needs to be done?

Dr. ROBERTS. Yes, sir, precisely. As a matter of fact, if NCAR were looked upon as an alternative to the support of atmospheric science through the grants programs in the universities and so on, NCAR would not be serving its objective, and it would then be inappropriate to continue the support of NCAR in the National Science Foundation.

Mr. DADDARIO. This was what you were referring to, then, Father Hesburgh?

Father HESBURGH. Exactly.

Mr. DADDARIO. We have got to be careful how we maintain the balance within the development of the National Science Foundation, recognizing the need which Dr. Roberts has brought out in such areas as this.

Father HESBURGH. That is right.

Dr. ROBERTS. The entire budget and the entire planning of NCAR must run the hurdle of UCAR Council scrutiny, it must then come to the UCAR Board of Trustees, and it must be adopted by the Board of Trustees as representing the consensus of these people as to what NCAR should be, so that in a sense as university members they are looking at the benefit to their own activity, and I reiterate repeatedly to them that in my view they must see this as a benefit to the growth of the university work in atmospheric sciences.

Mr. DADDARIO. Do you have a question, Mr. Yeager?

Mr. YEAGER. Perhaps I had better submit this for the record.[1]

Mr. DADDARIO. I want to thank you, Dr. Roberts and Father Hesburgh for having made this such an informative morning. The help you gave us I am sure will reflect itself as we continue these hearings. We will be in touch with both of you so far as additional queries are concerned.

This committee will adjourn until tomorrow morning at 10 o'clock at the same place.

(Whereupon, at 12:30 p.m., the subcommittee was adjourned to reconvene at 10 a.m., Thursday, July 22, 1965.)

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

THURSDAY, JULY 22, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order.

Our first witness this morning is Dr. S. Dillon Ripley, who is the distinguished Secretary of the Smithsonian Institution. He is well known to us on this committee, both in his present capacity and as the past Director of Yale's Peabody Museum of Natural History for a long period of time. We are happy to have you here Dr. Ripley.

STATEMENT OF DR. S. DILLON RIPLEY, SECRETARY, SMITHSONIAN INSTITUTION

Dr. Ripley. Thank you very much, Mr. Chairman. I am delighted to be here today to address the Subcommittee on Science, Research, and Development. I want to say what a pleasure it is for me as Secretary of the Smithsonian to have been asked to come and testify and to discuss the National Science Foundation from the standpoint of the Smithsonian.

I should like to begin with some comments on the similarities and differences between the Smithsonian and the NSF, discuss the present situation of the NSF with reference to the position of basic research in the Nation, and conclude with a brief discussion of the Science Information Exchange, one of our principal common enterprises.

I. THE SMITHSONIAN AND THE NSF—SIMILARITIES AND DIFFERENCES

The Smithsonian Institution was constituted as an independent establishment under the Government of the United States "for the increase and diffusion of knowledge among men." Prof. Joseph Henry, the first Secretary, strove ardently to address the Institution's efforts to the improvement of basic research, especially experimental science, at a time when there were no laboratories in the United States devoted to such investigations. While the original Smithson bequest seemed magnificent to most, Henry was keenly aware that it was a limited sum that would soon disappear or lose its forces if the Smithsonian assumed the burden of major national programs.

Rather than become a service organization for others, like a library or mere repository of objects, or a college to offer instruction in what was already known, it was Henry's view that the Smithsonian should be devoted to the acquisition of new knowledge and its dissemination to learned societies and academies throughout the world. Through its laboratories and lecture halls the Smithsonian became a forerunner of the modern graduate university. It was dedicated to the improvement of basic research in America by helping to establish unfamiliar fields of study, maintaining groups of investigators in especially worthwhile areas and championing the idea of the disinterested pursuit of knowledge for its own sake.

The National Science Foundation, also established to improve the situation of basic research, reflected the thinking of Vannevar Bush's famous study, "Science—the Endless Frontier," which focuses concern on the overall level of effort in basic research in the Nation as a whole, urging that:

> The Government should accept new responsibilities for promoting the flow of new scientific knowledge and the development of scientific talent in our youth.

The Smithsonian still retains a general concern for the situation of basic research. That responsibility is met through activities undertaken directly by the Institution, not by making financial support generally available to the scientific community.

If the Smithsonian enjoyed a brief monopoly as the principal basic research organization in the United States that position has been cheerfully foregone as our great national complex of research organizations came into being. Where needs have existed for an organization to perform specific tasks in research the Smithsonian has often responded. But its focus is upon pinpointed requirements rather than generalized levels of support.

For example, when it became apparent that large-scale flood control projects in the American West would jeopardize important archeological sites the Smithsonian organized a national program of salvage archeology as a joint project with the Department of the Interior. Prior to the International Geophysical Year astronomers recognized the need for a system of visual satellite tracking stations, now operated in 10 countries by the Smithsonian Astrophysical Observatory. For many years the Institution's Radiation Biology Laboratory has undertaken to compute the solar constant and calibrate measuring devices for solar radiation. The National Zoological Park was the first zoo to be devoted to the preservation and breeding of rare and endangered species, a lively concern today which dates back to Secretary Baird, who tethered bison on the Mall and saw to it that a breeding herd was kept. The Smithsonian Oceanographic Sorting Center has been created to refer specimens collected in the national marine biology program to appropriate specialists all over the world for analysis and identification. These are but a few examples of specific Smithsonian responses to national needs in basic research.

The National Science Foundation is concerned with all fields of science, while the Smithsonian has restricted its activities to a range of rather specific disciplines. In the sciences these are astrophysics and earth sciences, anthropology, marine biology, systematic biology, and environmental biology. Among the humanities these are his-

tory, fine arts, and portraiture, with special reference to American studies. In addition, the Smithsonian has given prominence to the operation of museums, galleries, and other forms of exhibition for the enlightenment of the public. Thus a number of its programs in scientific research and scholarship are oriented toward support for the museum activities of the Institution. It might be said that the research efforts of the Smithsonian come to a focus in three central, classical concerns of science; the nature of the universe, the organization of life, and the nature and history of man's culture.

While the Smithsonian's tradition is that of the direct performance of research, it has not been limited to in-house activities. It formerly awarded premiums for distinguished research and has always been one of America's foremost scientific publishing houses. The predecessors of today's Environmental Science Services Administration, Fish and Wildlife Service, and NASA all began as Smithsonian activities that were spun off, as it were, into independence as their scientific potential justified the development of mission-oriented Government agencies. While the Institution might be said to provide extramural support on occasion, this is usually where the investigator's activity is directly related to projects underway within the Institution. Such support may involve specific contracts for the performance of services or loans of specimens from the national collections. Those who perform the work might be said to be agents, rather than beneficiaries, of the Institution, which itself benefits from having the work carried out.

Today there is increasing interest in extramural activities, from research contracts to fellowships, in tropical biology, the museum professions, anthropology, fine arts, and marine biology. The Institution has recently begun a program of grants of excess currencies with reference to museum programs and associated research in archeology, the natural sciences, and cultural history.

The Smithsonian has on numerous occasions received NSF support. One category of grants has been for research projects of individual Smithsonian staff members. So long as the prohibition against transfers of NSF funds for research in agencies receiving appropriated funds continues in force, the Smithsonian will not receive NSF grants for this purpose. It is contemplated, however, that grants and contracts for educational services, information services, and participation in national programs funded by the NSF will continue. At the present time these include funds for visiting research appointments for undergraduate science students, the support of the Science Information Exchange, and a number of projects in oceanography and Antarctic research. I may add that the endorsement of Smithsonian activities by NSF panels, the service of Smithsonian staff members in reviewing proposals, and our mutual participation in considering national research needs has resulted in a highly gratifying partnership between the Smithsonian and the NSF in a host of instances. We have greatly enjoyed and profited from these associations.

In the last analysis, the level of support and range of activities of the Smithsonian reflects opportunities for significant research. The level of support for the NSF reflects, or should reflect, the situation of science in the Nation. It might be said that the Smithsonian is able to concentrate on its own institutional objectives where the NSF or other supporting agencies have met national needs adequately.

II. THE NSF AND NATIONAL NEEDS IN BASIC RESEARCH

It was my privilege to have one of the first National Science Foundation grants, for the study of the birds of continental and southeast Asia. My direct experience of NSF granting programs has continued in a number of museums and universities. The Foundation has never taken a narrow view of its charter. Grants have been made available to investigators in different kinds of institutions: to scientific societies, publication projects, and other categories. The Foundation has had remarkable leadership and a distinguished staff. It has responded courageously to the demands of scientific freedom in the terms of support and projects chosen. It has helped to promote a truly astonishing civic spirit in science whereby the members of the scientific community give generously of their time and advice through a consultant and panel system that I believe to be unique in the annals of Government. It has demonstrated its fitness for its mission of promoting the development of basic research in the national interest. I recommend that this subcommittee consider means of enabling the Foundation to respond more effectively to the situation of basic research in our society.

As Dr. Haworth pointed out earlier in these hearings, the NSF is unable to support all projects deemed worthy of support. And the average successful project is reduced in dollar amount or in term of years when a grant is made. Not until the Foundation comes abreast of the financial needs of basic research will it be properly situated to fulfill its function. The Foundation must be placed in the position of being able to assess national need and propose remedies. At present it must struggle to adapt too little money to a hopelessly broad series of objectives. We have substituted an artificial financial level for the national standard that the NSF was constituted to maintain. In my view the Foundation has not yet been able to operate as it should, which would be by translating the Nation's needs for basic research into programs of Government support. The first imperative is a rapid and decisive phase of growth well beyond its present dollar level. Other witnesses have used the figure of $1 billion. I agree with them. I wish to underscore this recommendation in three ways:

First, much has been said, in the National Academy report and in testimony, about adopting a basic research growth rate of 15 percent per year. That figure is based upon two factors, needed growth in graduate education at a rate of 8 to 10 percent per year, and increased costs in research of 5 to 7 percent per year. I agree with the 15 percent figure and believe its adoption would be desirable. But the present Foundation budget is too small to be a sufficient base upon which the addition of 15 percent each year would accomplish the Foundation's overall objectives.

Second, we must not rely on applied research agencies or applied research tasks to yield of themselves an adequate return in basic knowledge. As Alvin Weinberg has told the subcommittee, the missions of the DOD, AEC, and NASA are not going to expand as rapidly as the needs for basic research and these agencies must not be relied upon to provide the funds we need. My attention was recently drawn to a statement by Goldsmith and Mackay in the introduction to their collection of essays. "The Science of Science," Souvenir Press, 1964.

They argue that "a general problem of social importance provides as good a beach for combing for the unplanned discovery as does complete freedom." Of course, this occasionally happens but there is no evidence to warrant a general conclusion that we should emphasize applied research and leave basic research to shift for itself. It would be a solecism in research policy to expect applied research to yield a sufficient return of basic knowledge.

Mr. DADDARIO. Dr. Ripley, in this regard, how do you see the function of such mission-oriented agencies in providing a certain level of basic research both for national purposes, and also to accomplish its own mission-oriented objectives? We have had some discussion of this, and I would like your opinion. Are you suggesting that the mission-oriented agencies should devote themselves only to applied research and have no basic function, and that this basic research function should be either controlled or performed by NSF?

Dr. RIPLEY. I think it is very hard to set up a kind of formula, mathematical formula, but my impression is, Mr. Chairman, that the experience of the past in science has shown that certain applied laboratories do produce—I used the word spin off earlier— spin off basic results, and I think it is almost impossible to assess how this process is going to come because it is essentially an intellectual process. If you have laboratories in operation with scientists who have essentially applied missions, they are bound to spin off and generate ideas which have basic value. You can't prevent it. On the other hand, I don't think you can estimate exactly what the proportion is going to be.

It is almost impossible to analyze. This is probably an unsatisfactory answer, but I have never been able to determine exactly what proportion of persons working in a laboratory with a mission can prevent themselves, as it were, from having ideas which are peripheral to the central mission, but which may be of a basic nature.

Mr. DADDARIO. The theory has been proposed during these hearings that the mission-oriented agencies need to perform basic research in order to help them achieve their objectives. Perhaps the corollary of that is also true, that in order to help give drive to its basic research, NSF ought to have an applied research responsibility. The question then if this happens, would NSF get into an area of activity within which there are so many inflexible elements that it could not maintain enough flexibility to perform its basic research function? I would like your view on that.

Dr. RIPLEY. My own premise would be that in regard to the basic research oriented laboratories or agencies, they should confine themselves essentially to basic research. It is very difficult to analyze a corollary series of applied missions. This is an area where we may find that in terms of environmental biology and environmental health there may be considerable overlap almost of necessity, and in this area I would be willing to hedge about the kinds of applied missions that I would see basic oriented agencies undertake.

Mr. DADDARIO. Could you go into that a little bit?

Dr. RIPLEY. Well, I am very much interested myself in terms of being a conservationist in the corollary problems of environmental biology which involve pollution and use of pesticides and activities of this sort. Instantly when one gets into analyses of these which may be basically directed one tends to find oneself—perhaps coordinating

would be a better word rather than overlapping—coordinating with a number of other activities which may be of an applied nature. That is what I mean.

Mr. DADDARIO. Fine, thank you.

Dr. RIPLEY. It is sometimes said that we have an unused surplus of knowledge that has resulted from basic research—that there are more good scientific ideas on hand than can be followed up for purposes of applied R. & D. I think this is quite incorrect. Even in applied research fields themselves, although I am not an expert in technology, it appears that many processes and devices are unnecessarily primitive for lack of the necessary scientific understanding. If this were not the case, why would applied research agencies such as the DOD or private industry have to support some basic research in related fields?

Even more important, Mr. Chairman, is the fact that man's knowledge supports abundant intuitions of new areas of investigation that cannot be properly followed up, for lack of trained investigators and lack of funds. We are not progressing sufficiently rapidly in our investigations of life processes, chemistry, human psychology, and physical processes at all levels. At the Smithsonian I feel every day the enormous urgency of such matters as the need to study species and environments that may disappear before man has indeed learned their secrets, or cultures that will disappear before they are understood or even placed on record.

In a very real sense the process of setting a proper level for the National Science Foundation requires us to answer the question, "How much science?"

This subcommittee has contributed a great deal to public discussion of this question. It is one that the Smithsonian Institution was created to engage. The starting point for my answer is not the digestive capacity of science-oriented industry, or the needs of graduate education. It is the situation of knowledge. Dr. Johnson said we would all rather know a fact than not know it. Well, I would not be quite so matter of fact. We cannot, for example, insist that the developing nations cease to clear their jungles until we have learned the precise location of all the undescribed species of snails. Science must not be permitted to claim an overlarge share of public resources. So there is a need for balancing competing claims and a wide public discussion of how to strike that balance has already begun.

We welcome the public discussion of our national policy for science, believing that a positive desire for new knowledge must be widely shared among the people before it can be secure among the aims of government. This Institution has been a champion of basic research since its foundation, but its responsibility is not to ask for more just because this is a built-in-institutional precept. We would be responsible for saying we have done enough if that were indeed the case. I am here today to state that we have not done enough.

We spend $10 per inhabitant per year in the United States on basic research. We spend perhaps 10 times as much on all research and development. We might think of all R. & D. as involving cigarette money; basic research costs the average citizen about as much as his chewing gum. If you all insist on chewing gum. These are homely comparisons. I have heard it said that all spending for basic research since the beginning of science equals the value added by the

world's industrial establishment to it raw materials in each 5-day period. Surely we are not saying that we have begun to approach the limits of our ability to finance basic research, when such investments are minor in themselves and almost inevitably repay us many times over. The limits have always been too few laboratories, too few teachers to produce new scientists, and too few opportunities for our people to receive training. Indeed the NSF has been charged with expanding just exactly these opportunities.

In a democracy the limit upon pure science should not be what the government chooses to spend, but the public's appetite to know. Where more young men and women would elect scientific careers than have the opportunity to pursue their inclination, we have too little science. Where the Nation's community of scientists wish to pursue their chosen investigations, and these are found to have merit, it is lamentable that public authorities should deny them the opportunity. The National Science Foundation Act authorized and directs the Foundation to—

initiate and support basic scientific research and programs to strengthen scientific research potential in the mathematical, physical, medical, biological, engineering, and other sciences.

The act and the reports that preceded its adoption are instinct with the notion that the Foundation would devote its efforts to discovering a proper level of support for basic research. In a very real sense, Mr. Chairman, the Foundation does not operate by answering that question. It does its best—and it is a very good job indeed—with the resources at its disposal. But the level of resources available has not reflected the situation of basic research in our society—only the ability of one agency among several to secure funds. I find this a cruel paradox and an altogether inadequate response on the part of our society to opportunities for the very best kind of public investment we have yet learned how to make.

I wish to comment on another aspect of the Foundation's present situation, and I do so because this has greatly affected the tradition and history of the Smithsonian. The need for funds is matched by a need to maintain administrative flexibility in dispensing them. The Foundation should never be locked in to a few specified categories of activity, a geographical formula, or devices for support that constrain the investigator.

The choice of the word "Foundation" for the NSF presumably reflected a conviction on the part of Congress and its advisers to maintain the utmost in flexibility, just as in the world of the great private foundations. I believe that the Foundation should be trusted to devise its own formulas for cost sharing and overhead, to choose its own management procedures, and to arrive at its own determinations about areas for support.

There is no surer way to devalue the Federal research dollar than to tie it to unwise or unduly rigid administrative requirements. The scientific literature is nowadays replete with expressions of concern on this score. If we are wise we will entrust the Foundation with maximum administrative latitude. It is easy to buy effort in research; it is far more difficult to provide for scientific results.

For 119 years the Smithsonian Institution has been centrally involved in our Nation's scientific and cultural life. Throughout this

time it has been guided by the wise advice of the scientific community and by the powerful traditions of science itself. I find in observing the National Science Foundation and in becoming acquainted with its staff the same traditions of quality and freedom, the same integrity of judgment, and the same dependence upon advice widely and freely given. To the extent I am able to judge the Foundation has made provision for a distinguished future. It seems sure to prove adequate to the challenge of the endless frontier. I believe that the time is at hand to provide secure guarantees of its national status as the principal agency of the Government for the support of basic research, and guarantees of the freedom and financial wherewithal that will permit it to discharge that mission.

III. THE SCIENCE INFORMATION EXCHANGE

I would like to speak, Mr. Chairman, for a moment about what we call the SIE, the Science Information Exchange. Fifteen years ago, foresighted research administrators of several Federal agencies agreed to pool information about their planned and on-going research activities, and to provide the funds to carry this out. This step was taken in 1949 in the interest of better research management in the face of rapidly rising research expenditure. Subsequent events have fully justified their anticipation and action.

Under the aegis of the Smithsonian Institution since 1953, a research information exchange system, known first as the Medical Science Information Exchange (MSIE), then as the Bio-Sciences Information Exchange (BSIE) and, since 1961, the Science Information Exchange (SIE), grew rapidly from a small collection of a few thousand records of currently active research tasks to the present office with a staff of 160 people and annual expenses of about $1½ million. In fiscal year 1965, SIE collected over 100,000 records of research proposals and active tasks and answered about 43,000 questions for all echelons of the scientific research community. The interest and requests for service continue to grow.

The unique feature of this pioneer venture has been its comprehensive store of information about research in its planning and progress phases long before it becomes accessible through the libraries, documentation centers, and technical journals that report only the completed results, often 1 to 3 years after the work actually started. The Exchange thus offers its users information about who is working on what specific research projects or problems, where, when, and with what level of effort. SIE now covers all fields of basic and applied research in the life, social, and physical sciences. Needless to say this information becomes an ever more valuable national archive of research. The highest priority should be given to its continued development.

While the highest priority for both the acquisition of records and provision of services is placed upon federally supported projects, the 1965 total of 70,000 currently active tasks included a substantial number voluntarily registered by some 200 private research organizations.

There are many ways in which this store of research information can be used, but the most immediate benefit to the Government is in avoiding duplication of support for a given project by learning from SIE whether it or a similar undertaking is already receiving support.

President Johnson's recent report on economy, war on waste, singled out the SIE for praise, saying:

> A busy scientist wishing to know what's going on currently in Federal research on the kinetics of conversion of anhydrous boron oxide to boron nitride can turn to the SIE for an up-to-date answer in detail—who is currently working on the problem, where, and with whose financial support. It can offer the same answering service for research that is being proposed or actually in progress in any science from astronomy to zoology. This clearinghouse on research project information conserves time, funds, and scarce scientific manpower.

The information is stored in the IBM 1460 computer on a unit basis (the "Notice of Research Project" form) and answers to widely varying types of inquiries may be selected and assembled. Questions range all the way from the inquiry of a single scientist about a single subject of investigation to the recent Presidential request to prepare the Water Resources Research Catalog, a 415-page indexed collection of over 1,400 Federal research projects in the general field of water resources research.

Over the years this service has grown steadily with considerable evidence of the users' acceptance and satisfaction. One of the principal conclusions of the Elliott committee was:

> The continued Federal support of SIE is deemed to be warranted. Its services, both to the scientific community at large and to research administrators, are clearly useful; as a tool for coordination and avoidance of needless duplication, it has already paid for itself many times over.[1]

Hundreds of letters from scientists and engineers in Government, universities, and industry have indicated their satisfaction, and of 500 users actually queried, 95 percent stated that they learned for the first time about new investigations or investigators in their own specialties through SIE.

For the first 14 years, the Exchange was governed by Federal agencies under a mutual agreement to share their research information and the costs of obtaining it. Authority and policy guidance resided in a Board of Governors whose members represented the participating agencies. When the annual cost of the Exchange rose over a million dollars annually, the interagency funding situation was judged inadequate and in 1963, the National Science Foundation was asked to provide the entire support on behalf of all the agencies and directed to continue the use of the Smithsonian Institution as the operating agency. The former operating board is now advisory to the NSF, which sets policy, scope, and procedures under a charter of agreement with the Smithsonian.

In a government whose operations must sometimes proceed according to regulations essentially unsuited to their purposes, the SIE is a noteworthy example of a self-reinforcing system that works almost automatically. As individual scientists and program directors in supporting organizations find SIE services helpful, they become more willing to provide the desired input of information about their own activities. This builds up a kind of mutualism, as it were, between the agencies providing the information and the scientists reporting to them, who become more willing to provide information once they find that the service works.

[1] U.S. House of Representatives, 88th Cong., 2d sess., committee print, Select Committee on Government Research, study No. I, "Administration of Research and Development Grants," p. 90.

The greater the volume of input, the more nearly complete the SIE answering service becomes in its coverage of any subject. Some Federal agencies have experienced difficulty in adapting their research project information systems to SIE requirements. The Committee on Scientific and Technical Information, of the Federal Council for Science and Technology, has been cognizant of this situation and is, I understand, taking steps to urge all agencies supporting research to report fully and on a current basis to the SIE.

I am committed to the continued development of the SIE, not only as a matter of sound Government operation, but because it promises to fill a gap that may become an ever more serious problem for science. As the volume of literature grows and it becomes less and less possible for scientists attending conferences to hear in person the papers of their colleagues, the scientist will be in danger of losing communication with his colleagues through simple ignorance of who they are or what they are doing. Already this problem has led some investigators, especially those in the foremost rank of workers on theoretical problems, to maintain mailing lists of colleagues in order to exchange mimeographed previews of forthcoming papers. These little "invisible colleges—usually small groups of specialists in advanced fields—usually include investigators of established reputation, but not the unrecognized scholar, or the man in a related discipline whose work has only recently become pertinent to the members of the actively communicating group.

In my own field of ecology, a man may actively work on a given problem for some years before a publication results; the old system of learning about such work from colleagues breaks down as the lines of communication become ever longer, involving the entire world and hundreds rather than dozens of fellow investigators. I find time after time if I write a paper on an ecological problem myself that three or four of my best friends and colleagues don't know I have written it, and I have to remind them anywhere, in a drug store or a scientific meeting, "Have you got that paper and why haven't I seen yours that somebody else told me about? This happens all the time. A "current awareness" information scheme such as that of the SIE is likely to be of the utmost value in maintaining the traditional open community aspect of science.

In concluding, Mr. Chairman, let me return to a question raised earlier. Is there too much science? Let me say at the outset that the Smithsonian and other museums and related institutions have a great responsibility to help educate members of the public to appreciate the vast scope of man's knowledge. This theme—man's knowledge—has, for example, been chosen as the theme of this year's celebration at the Smithsonian of the bicentennial of the birth of the Institution's founder, James Smithson, whose famous bequest led to the establishment of the Smithsonian. We ardently hope that the 14 million visitors to our buildings, and the 200 million who visit the museums of the Nation each year, grow in their understanding of our present age of science. Much more is to be done, with new exhibits techniques and the development of radio and educational television. We should resolve that knowledge shall be advanced but not beyond the reach of the citizen.

Ultimately, I believe that the advances of science will be for the citizen what they have been for the scientific community, one of the most remarkable achievements of our civilization and a redeeming feature of man's still brief tenure of the planet. To preserve himself and meet the challenges of constant change, man's knowledge must grow at an ever-increasing rate. I feel that I must answer my own question by saying that there can probably never be enough science, and that our need for the National Science Foundation will be a mounting and continuing one. I respectfully suggest that this subcommittee consider what man would lose in stature if his questions ever were entirely answered, if he ceased his quest for new knowledge, or lost faith in his ability to capture it from the unknown.

I should like to conclude by showing that a great deal of this is current, but a great deal of it has always been current in our Nation. I am quoting from the eighth annual report of the Smithsonian in 1853 and the words of Prof. Joseph Henry, the physicist who became its first Secretary. He said:

> There is another division with regard to knowledge which Smithson does not embrace in his design, viz: the application of knowledge to useful purposes in the arts: and it was not necessary he should found an institution for this purpose. There are already in every civilized country establishments and patent laws for the encouragement of this department of mental industry. As soon as any branch of science can be brought to bear on the necessities, conveniences, or luxuries of life, it meets with encouragement and reward. Not so with the discovery of the incipient principles of science. The investigations which lead to these receive no fostering care from government, and are considered by the superficial observer as trifles unworthy the attention of those who place the supreme good in that which immediately administers to the physical necessities or luxuries of life.

Thank you very much, Mr. Chairman.

Mr. DADDARIO. Thank you, doctor.

Mr. Vivian.

Mr. VIVIAN. I must comment on your remarks about the SIE. You say:

> The problem has led some investigators, especially those in the foremost rank of workers on theoretical problems, to maintain mailing lists of colleagues in order to exchange mimeographed previews of forthcoming papers.

That is an extremely familiar subject. I think I threw away most of my mailing lists a while back. I would like to point out that it cost the Federal Government a fair amount of money to maintain those mailing lists since many of the persons are being paid for Federal research activities, and they are using secretarial time and their own personal time. I had, for example, so-called McBee file for a number of years which was a very poor approximation to your computer file. I think an extension of the Science Information Exchange could be a very great asset. However, extension has to go not only to agencies but also to private researchers, and there are several hundred thousand in this category, so that you may have to reproduce several hundred thousand items. Probably the only inexpensive way of doing this is through a centralized system. What concerns me about the SIE system, which I think is basically an excellent approach, is the following: How often do you report back to the investigators or to the sponsoring agencies, the agencies one step above the individual investigators, what the SIE says they are doing?

Dr. RIPLEY. I think this is a tailormade operation. In certain instances the agencies ask for an overview of what they are doing, and that this is—I am not sure if it is exactly scheduled at this point, so that by "tailor made" I mean that it comes and goes. In some cases agencies do ask for overviews and reviews and in some cases they may wait for a while. In many cases it is done by interagency exchange at meetings. The SIE sponsors meetings with the agency heads and during this time present reports about the current product. That sort of thing is visualized.

Mr. VIVIAN. I would like to stress that you will not have really an efficient system for SIE until it is down to the individual level because within many organizations there are significant differences between individuals. If you do not have an automatic report-back procedure which shows how the entry looks on the SIE files, you will miss an enormous amount of valuable work. This happens very frequently.

Dr. RIPLEY. We do have that, Congressman Vivian. I know, for example, when I am doing something I get one of these forms to fill out, and this is quite automatic. This is sent back and dovetailed into the general information file and then summaries of these are brought together at these meetings. So I think they are very well aware that you can't ever let the information lie fallow, and certainly as an individual investigator, as probably you yourself experienced, one does get these forms once a year from the agency asking you to get the forms back in and give summaries.

Mr. VIVIAN. Let me ask a question: I will localize it simply for pertinence. Suppose I were to pick up the phone book, say, for the University of Michigan in my district and I was to arbitrarily pick the 10th name down the list in the department of physiology. Assuming he is performing research, if I asked him if a record of his investigation is held in SIE, is he likely to say yes or no, and is he likely to know what is held there?

Dr. RIPLEY. He is likely to say "Yes." You can't force these people to do it.

Mr. VIVIAN. I understand that.

Dr. RIPLEY. He is likely to say "Yes" and he is likely to have had some communications within the past 6 months implying that there is an awareness on their part that he is doing this and a desire by them to get information back into the system.

Mr. VIVIAN. Has he ever seen a report back of what supposedly he is doing?

Dr. RIPLEY. Yes.

Mr. VIVIAN. He has actually seen a record?

Dr. RIPLEY. Yes; he should have. Yes, you receive each year a duplicate of your project notices to be revised as needed.

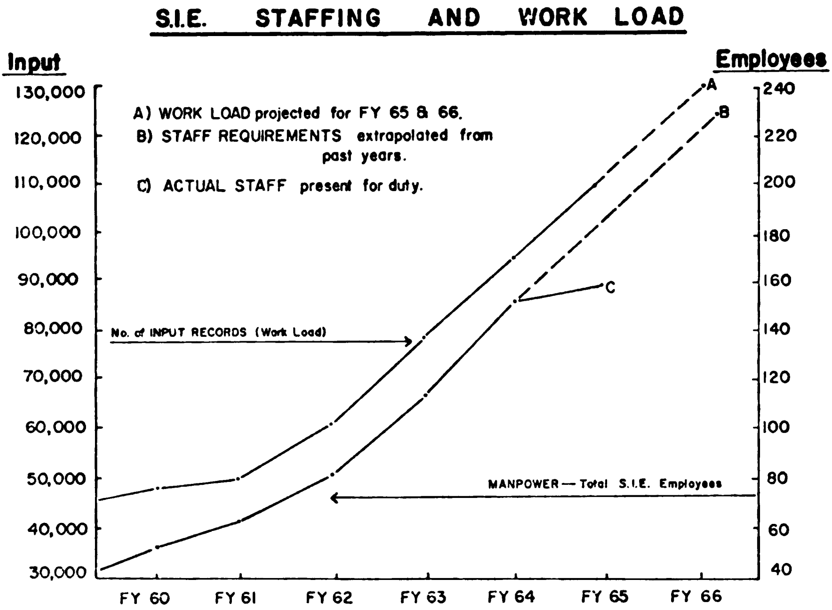
Mr. VIVIAN. But he actually does receive this report back?

Dr. RIPLEY. He should, yes; if he hasn't dropped it in the wastebasket or done something which is a factor of human error involved.

Mr. VIVIAN. I will try to go down a list in a telephone book and take 10 names and see how we run out on this matter.

Dr. RIPLEY. We have some of these tables on the operations and workload of the SIE, and I would be very glad to enter them into the record showing some of the feedback process involved, which I think is what we have been discussing.

(The information referred to follows:)



SCIENCE INFORMATION EXCHANGE

Budget and personnel, fiscal years 1961–65

	During period	Funding
Personnel employed:		
62–65	1960–61	643, 089
65–87	1961–62	850, 000
87–127	1962–63	1, 000, 000
127–153	1963–64	1, 500, 000
153–160	1964–65	2, 000, 000

SIE operations, fiscal years 1964–65

	1964	1965
INPUT		
Projects processed	69, 500	[1] 75, 463
Proposals processed	25, 312	25, 717
OUTPUT		
Major special projects (100 percent Federal requestors)	7	16
Administrative compilations (87 percent Federal requestors)	114	159
Subject questions (79 percent Federal) [2]	4, 413	5, 341
Investigator reports (93 percent Federal requestors)	29, 476	38, 110
Automatic distribution (99 percent Federal requestors)	356, 779	430, 084
Total NRP's distributed (all services)	697, 135	865, 976

[1] Basic DOD fiscal year 1965 research records promised for August 1965, not included.
[2] The SIE log of 792 subject requests for sample period April–May–June 1964 actually shows the following data:

36 percent were from Federal Government officials and employees;
25 percent were from Federal contractors or grantees (including nonprofit and industrial laboratories);
18 percent were from laboratories that had Federal grants or contracts in the same subject fields requested (including nonprofit and industrial laboratories);
21 percent were from sources not identifiable as Federally supportive. Therefore, 79 percent of the subject requests were geared to the Federal research program.

General Significance of SIE Compilations

Compilations of data from Science Information Exchange (SIE) are subject to some inherent limitations and exceptions. Wherever possible, SIE will note and estimate the significance of these conditions as they apply to each compilation. There are also the general limitations noted below that should be recognized in order to avoid possible misinterpretation, confusion, and contradictory conclusions, when comparing these data with other sources.

SIE is an inventory of research tasks, where "task" means a small uniquely identified unit of research work.

The dollar values recorded by SIE are intended only to show the annual level of effort (or support) for each individual task.

Sums, totals, and compilations of SIE's research task records are not designed to reflect budget data. Therefore, SIE dollar sums and totals cannot be reconciled with budgets that are essentially inventories of total dollars. The latter allocates all R. & D. dollars to specified categories. SIE counts only those dollars that are annually allocated to a selected list of items identified as basic and applied research tasks. This does not include many categories of overhead, general support, construction, fellowships, etc.

SIE dollar sums and totals can be used as a comparative index of relative emphasis and distribution among agencies, or recipients, or geographical areas, of subject fields, etc., for one or a series of years, if the inherent limitations and exceptions are clearly recognized in each case and applied to the derivation of conclusions. For example:

(1) SIE receives no research records classified for national security.

(2) SIE receives no dollar values for most in-house research tasks.

(3) At this time, SIE receives few records of development projects and programs.

In comparing SIE data with other sources, it should be noted that many projects and tasks are on the borderline between applied research, advanced technology, and development. The decision for inclusion or exclusion is arbitrary, and may differ among agencies, and by individuals. These may total fairly large sums, and corresponding discrepancies.

(4) SIE focuses on the research task, per se. Contracts, grants, and funds allocated to general research support, such as interdisciplinary laboratories, institutional grants, etc., that are not related to specific research tasks may not come to SIE or may be accounted differently.

(5) SIE registers research tasks according to the fiscal year in which the research began. This may or may not agree with the fiscal year in which the funds were budgeted, committed, or obligated.

(6) SIE records the annual cost (level of effort) for a grant or contract that may extend over several years. Some agencies assign the budget cost of a single 3-year grant to 1 fiscal year, in compiling their reports.

(7) SIE can only report on tasks that have been registered by the participating agencies. All Federal agencies do not register their entire programs so that SIE cannot guarantee complete coverage for any given program, subject, or agency.

(8) The SIE collection has grown rapidly over the years as agencies have initiated and/or increased their registration. Comparative trends over a series of years in some categories may reflect the growth of the Exchange rather than changing emphasis in the research area or program.

(9) With any compilation, SIE will note and estimate the significance of these limitations, as far as possible, if requested to do so.

Mr. VIVIAN. I have two other questions if time is available.

On page 10 of your remarks you indicate that—

> the Smithsonian welcomes a public discussion of our national policy for science, believing that a positive desire for new knowledge must be widely shared among the people before it can be secure among the aims of Government.

That is a very accurate statement. I would like to know whether or not you feel there are more productive things that can be done in this direction than are presently being done?

Dr. RIPLEY. I think there is room for always a continuing investigation and exchange of information at different levels in government on these subjects, and that is one reason I welcome these sorts of opportunities to discuss among Members of the Congress and ourselves the kinds of things we are carrying on. There is just so much one can do in any one time.

Mr. VIVIAN. Would you be more specific? NASA space launches such as Gemini are nationally televised. I am curious to know whether you feel the health sciences or the social sciences have similar access to the public interest.

Dr. RIPLEY. I don't suppose they really do. The health sciences do through the various sorts of exhibits of museums of science and industry and human biology exhibits and so on.

Mr. VIVIAN. Do you have any opportunity, for example, to present a television program once or twice a week, or do you have cooperative arrangements with university educational stations or with the major networks to disseminate information on some of the advances in the more human facets of science?

Dr. RIPLEY. We don't have as much opportunity as we would like. We have not particularly received support. The field of public information, so called, has always been one which seems to be suspect in the minds of government, and I might say we have not received as much support as we would like for this sort of thing.

Mr. VIVIAN. Do you have an authorization, for example, to prepare not only museum displays but also television shorts on various subjects? Do you have an authorization and budget for this purpose?

Dr. RIPLEY. We have an authorization but no budget for it. We have a blanket authorization which has allowed us in the past to cooperate with private radio, for example, in the preparation of a radio program which was quite successful but which for budgetary reasons we finally had to discontinue. I have been exploring at the present time methods of getting private contributions from foundations and business interests to try and get back into the field of educational radio and television.

Mr. VIVIAN. There is NET. They do work closely with the Smithsonian or not?

Dr. RIPLEY. No, not at this point. But we are presently preparing as a tickler, I might call it, a short movie which will be shown on television of some of the panorama of the development of American science in the 19th century, represented by the Smithsonian's activities, to be released at the time of the bicentennial in September. I think myself that this is enormously important and we should be involved.

Mr. VIVIAN. Mr. Chairman, I have several other questions, but I may be prohibiting other members from asking questions.

Mr. DADDARIO. I think you should continue.

Mr. VIVIAN. On page 9 you refer to a lack of sufficient progress or—

not progressing sufficiently rapidly in investigation of life processes, chemistry, human psychology, and physical processes at all levels.

There has been some previous discussion of that general subject. I am curious to know whether you think it is a result of the Government organizational structure at this time or some other situation. Is it because the governmental research organizations are not properly organized?

Dr. RIPLEY. I wouldn't say that at all. Always it seems we don't know enough about these agencies. The massive assaults in certain areas, investigations in life processes, chemistry and psychology and so on, has been tremendous. There is no doubt about it. The results haven't been coming in——

Mr. VIVIAN. Why do you use the words "not progressing sufficiently rapidly"?

Dr. RIPLEY. By "progressing" what I mean is essentially the results rather than the push toward the process. I think there have been in some areas, particularly health, tremendous thrusts toward solving the problems.

Mr. VIVIAN. Do you consider that the National Science Foundation is putting sufficient support on these particular subjects?

Dr. RIPLEY. I don't know that I want to speak to this as to the exact elements of the National Science Foundation and the National Science Institutes of Health. This is an area which I am not too familiar with. Certainly in areas of social psychology and environmental biology I feel we are not getting enough support and that probably processes and investigations could be furthered by more support. This is the sort of thing I think the NCF, if given more funds, could do very profitably.

Mr. VIVIAN. On page 4 you indicate:

The research efforts of the Smithsonian come to a focus in three areas, the nature of the university, the organization of life, and nature and history of man's culture.

It is my general feeling that the Smithsonian stresses the last of those three, and that the Smithsonian is the historian of the scientific world. The previous remarks you made on the Smithsonian being active in astrophysics, earth sciences, and marine biology, suggests that you view your role as being more than historical. I gather that is the case.

Dr. RIPLEY. Yes, that is the case.

Mr. VIVIAN. What percentage of your budget would fit into what I will call the nonhistorical category? I am interpreting history in the broad context.

Dr. RIPLEY. Actually about a third; no, a little more than a third, nearly 35 percent, of our budget goes into natural science and research plus, of course, we get additional grants from NASA, for example, and other agencies for performing missions and tasks for them.

This is perhaps an outgrowth of the familiar concept in the public mind, as well as in scientists' minds, of the word "museum." It has a kind of strange dead connotation, and it implies at best a historical approach toward knowledge and the accumulation of knowledge, and, of course, the Smithsonian is very much more than a museum. In this sense it is like an iceberg; $8 million of our annual budget are involved in original research and related improvements in physical plant.

Mr. VIVIAN. I understand you have been active in astrophysics. I am also aware that the Smithsonian is used for some of the tracking activities in the space program. However, I have the feeling that the astrophysics work might drift more toward NASA at the present time or into NSF's general support rather than being continued actively by the Smithsonian. I realize that may not be to your interest or liking, but do you not perhaps see your role changing from what might have been quiet science becoming suddenly active?

Dr. RIPLEY. I think the Smithsonian's interest in astrophysics, which is historical and old, has kept up very well with present developments. We have people on our staff who have been working for years in the area of meteoretics, tektites, and the analysis of material which has arrived from outer space. We have people working in radiation biology directly as an outgrowth of our own interests in astrophysics who are performing I would say not only adequately but

inventively, originally, and basically in areas which are keeping up very nicely with the general field.

Mr. VIVIAN. What other agencies in the Government today are specializing in astrophysics? I would assume NASA and NSF are active in that area.

Dr. RIPLEY. NSF in a granting form but not performing original research perhaps. We are concerned with performing research ourselves.

Mr. VIVIAN. What other agencies would be involved, other than the two I mentioned?

Dr. RIPLEY. I suppose NASA and—let's see—the Joint Institute for Laboratory Astrophysics of the Bureau of Standards, at Boulder. There is also NASA's Goddard Institute for Space Studies in New York.

Mr. VIVIAN. Any others?

Dr. RIPLEY. Perhaps I should mention Dr. Friedman at the Naval Research Laboratory and its Hulbert Center.

Mr. VIVIAN. So it is not an overpopulated field at the present moment?

Dr. RIPLEY. No, it is not a terribly overcomplicated field I would say. I think we are maintaining, as I say, a gradual growth of our own which is traditional but also capable of innovation. I would say that at such point as it becomes applied or it becomes very widely of importance we would be prepared to spin it off as we have continually spun things off in the past.

Mr. VIVIAN. Do you still operate the tracking station which you were very deeply involved in awhile back?

Dr. RIPLEY. Yes. We have these Baker-Nunn cameras which were set up under an original NSF grant as a result of our own investigations and research which we operate, largely as a series of cooperative arrangements with NASA.

Mr. VIVIAN. Thank you, Mr. Chairman.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Doctor, on page 8, you say our base is not large enough, and that an increase of 15 percent per year is all very well, but we do not have a sufficient base to start with. How should we go about establishing an acceptable base?

How can we do this, for instance, without materially affecting the quality of the work being done?

Dr. RIPLEY. I would say that the NSF must be in an excellent position to recommend, if they will, what kind of a base they would like to leap to. This is something for which they must have adequate statistics and figures, and if they choose to recommend a base, then, based on my experience of operating with them as an individual and as the head of an agency more recently, I would be inclined to agree with them. I agree with you that it is very difficult to analyze exactly at what moment there are enough investigations in prospect and investigators to perform them to sum a figure and say this is the kind of base that we need, but I would assume that NSF itself would be qualified to say that.

Mr. BROWN. Would you yield at that point?

Mr. CONABLE. Yes, I would.

Mr. BROWN. I would just like to translate this base into another framework. Actually when you talk about a base, all you are talking about is a timelag here. A 15-percent per year increase produces the base you are talking about in 5 years, so what we are really talking about is a 5-year timelag. I think our comments should be at least in part directed to the significance of whether this 5-year timelag is having a serious effect on our position in basic research.

Mr. DADDARIO. Would you comment on that?

Dr. RIPLEY. I know graduate students, I still have some, and I have had a lot of them, and I know how rapidly or not they tend to come down the pike, and I would say a 5-year lag is a critical lag. Fifteen percent per year would not make a sufficient contribution to the national level of effort.

Mr. DADDARIO. The budget which NSF submitted this year has been cut some $50 million. You would suggest that this would illustrate NSF's intention with regard to establishing a proper base?

Dr. RIPLEY. Very much so. Very much so indeed.

Mr. CONABLE. Doctor, I also note that you say:

> I believe that the time is at hand to provide secure guarantees of its national status as the principal agency of the Government for the support of basic research, guarantees of the freedom, and financial wherewithal that would permit it to discharge that mission.

What is the function of this committee in carrying out these guarantees? What would you like to see us do? What would you expect of us in this goal that you have set of a more secure position?

Dr. RIPLEY. I would say it is essentially a mood in any case, in thinking about it, a mood of generous willingness to support the science rather than specific details whether or not the degrees of reporting and accounting procedures are sufficiently strict or sufficiently lax or things of this sort. I think having worked with grants of different sorts, I cannot help but resent bitterly the kind of grant component which requires one to reply exactly how many minutes a day one has been at one's desk and when one has turned to the left or the right to answer the telephone or gone out to get a glass of water and for similar purposes, or talked to someone else who was not part of the grant funded procedures or talked to a student who came into the room by accident to ask a question, things of this sort. This kind of looking over the shoulder 1984 technique is the kind of thing in a sense that tends to compound the situation and produce petty bureaucrats and petty administrators out of people who I hope would otherwise continue to be scientists.

Mr. CONABLE. Do you feel that the scientific community resents in any way this investigation of the National Science Foundation that is going on now or do they understand that its purposes are broad in scope?

Dr. RIPLEY. I think they would be tremendously thrilled by it and greatly excited. I can't but feel always tremendously encouraged when committees of this sort do have this sort of honest and sensible inquiry. I think it is wonderful and I would hope all my colleagues felt the same way. I assume they would.

Mr. CONABLE. You are looking for us only to set a mood of support and of understanding?

Dr. RIPLEY. I assume in an atmosphere of mutual enthusiasm. This is great work, of great excitement, and of great importance to the future.

Mr. CONABLE. I think we are pretty well aware of the germinable characteristics which this agency has, and we are approaching this investigation in that mood. That is all I have, Mr. Chairman.

Mr. DADDARIO. I think Mr. Conable raises a very good point, Dr. Ripley, regarding the idea that a discussion must take place to create this atmosphere and this confidence.

This committee recommended that the percentage limitation on indirect overhead costs on research grants to universities be eliminated. We were able to make an impression within the Congress that this step should be taken, and the Appropriations Committee then took the steps to eliminate this provision in the appropriation acts for Federal agencies. It is, I think, an indication of confidence necessary to establish between ourselves and the scientific community. I would hope that this investigation of NSF would be a further step in that direction.

Mr. Brown.

Mr. BROWN. What size is the budget of the Smithsonian.

Mr. CONABLE. It is $22 million.

Dr. RIPLEY. Yes. This year it is about $22 million, Government supported operating expenses, exclusive of grants, buildings, and of our private endowments.

These are all published in our annual reports.

Mr. BROWN. In connection with the Science Information Exchange, we face a continuing problem in the overall proliferation of knowledge and in attempting to record it, and we face the administrative problem of how to coordinate this program and make it more effective. This raises the question in my mind as to the relationship between the Science Information Exchange and the other agencies of Government which are seeking to serve as centers for the dissemination of information. The Department of Commerce, for example, has a Technical Information Service which they recently opened. There are technology utilization programs in NASA, AEC, and DOD. The Science Information Exchange reports information about research in progress. This research is subsequently completed and then this moves into the field of possible technology.

Is there a problem with regard to making a coordinated whole of this process? Is there a problem of overlap, or are there areas which are not being covered in this total effort to provide information about science and technology?

Dr. RIPLEY. I would be inclined to think that our central theme is toward essentially basic research, and let the devil take the hindmost, as it were, beyond that, what comes out beyond that. I would assume that the Department of Commerce's activities are oriented in an entirely different framework, much more toward commerce, trade, technology, business, as it were, results. It is hard to conceive that there would not be possible overlaps but hard to conceive that at the same time the missions are not separate. I think it is very hard to say exactly what overlap there might be, but I would not view it as a threat because the essential importance of the information exchange type activity is that it must be done, and if it isn't done, that in itself

will be a calamity, so long as it is done and relatively well done, this is the thrust, this is the impetus for getting this thing out. I would hope that the agencies who for various reasons of security or concern about dissemination of information and so on, such as the areas that are a little more sensitive, defense, atomic energy, and so on, will gradually realize there are large components of this sort of information which can be fed into our Science Information Exchange. As I said in my testimony, these things feed on each other. The more information is given to the information exchange by an agency, the more willing they are to have an input and outflow with it, the more they then understand it, and the more they become enthusiastic about it.

Mr. BROWN. The point I am getting at is do we need to do more than to just assume this is a natural process which eventuates in a satisfactory system? In all of these other programs in the mission-oriented agencies there is a mix of material, there is basic research, there is applied research, there is technology. Some of it you might not feel should go into the Science Information Exchange, but it is all part of knowledge that is being accumulated. The overriding problem is how do we secure the optimum coordination of this tremendous flow of knowledge—the foreign journals, the reports of research in this country, all of these things. Now, I have heard that the systems being used in some of these agencies for the mechanical or electronic recording of this data are not completely compatible. You cannot use the same system to extract information from one that you can from the other. To a nontechnician in this field, this might be frustrating. Do you feel this is a problem or an area in which additional effort should be made?

Dr. RIPLEY. I feel, Mr. Brown, it is worth while pointing out that there are two slightly different principles involved here. Our Science Information Exchange, working with NSF, is really concerned in just trying to make everybody aware of what is going on right now. Most of the mission-oriented agency kinds of reporting procedures are concerned with what has already been put out. There is a difference. One is kind of a current awareness. The other is summarizing and reporting on documentation that has been produced.

Mr. BROWN. At what point do you cast out all of the material with regard to a given current research project? When it is published?

Dr. RIPLEY. No, we store it. We simply store it for retrieval. But that is easy enough on a card system, a computer system.

Mr. BROWN. Then over a period of time your files do not reflect what is currently in progress. It reflects a whole mass of stored information that is already reported in journals and so forth; is that not right?

Dr. RIPLEY. Yes. But is there anything wrong with that?

Mr. BROWN. No, but the point I am making is that this is what the other systems are doing.

Dr. RIPLEY. No, they are essentially involved in technology in other areas than basic research, and they are not building a current awareness file. It is the current awareness which starts off by being important. You don't necessarily want to throw away the card.

Mr. BROWN. Perhaps we are not adequately communicating with regard to the nature of this problem, but I do not want to belabor it.

Let me go into another area, one that Mr. Vivian mentioned; that is, the relationship of individual persons to this Science Information Exchange. Is there not also maintained by the NSF a roster of scientific and technical personnel which supposedly contains the names and backgrounds of scientific people, researchers, and so forth?

Dr. RIPLEY. Yes.

Mr. BROWN. Is there a relationship between this roster and the data which is kept in the Science Information Exchange?

Dr. RIPLEY. There is certainly a relationship, but I wouldn't say it is essentially overlapping, because the roster of personnel really involves bodies, and the current awareness program of SIE involved ideas, and the ideas may not always relate to the bodies in terms of the kind of information which you may wish to secure.

Mr. BROWN. You mentioned two areas that you said were not receiving an adequate amount of support. I think you said social psychology and environmental biology; is that right?

Dr. RIPLEY. Yes.

Mr. BROWN. And you referred to the support of the NSF and the Smithsonian?

Dr. RIPLEY. I assumed that the general NSF budget is reflected in the amount of funds that are then available to them to dispense in areas such as environmental biology. Social psychology comes over partly into NIH's interest.

Mr. BROWN. What do you mean by "environmental biology"?

Dr. RIPLEY. Environmental biology, as I visualize it, is the area where we are concerned with the relations of living organisms to their environment and the effects that the environment has upon living organisms. This is roughly what used to be called ecology, and ecology, which is a branch of biology, in which I happen to be very much interested, is essentially this concern or approach to an understanding of any living organism and the effect which it itself has on its environment and the effect which the environment has on it. This, of course, spans a very wide area of concern today especially.

Mr. BROWN. It is broad enough to include human beings then?

Dr. RIPLEY. Human ecology is certainly a little explored part of this.

Mr. BROWN. I raise the question because the subject has come up in previous hearings. I think we are all concerned about the effect of the environment on the fish and the birds, but living in Los Angeles I am a little concerned about the effect of smog on human beings and studies of that sort. I wonder if you would not agree that support for investigations in areas of this sort are perhaps at least equally important with research in the problems involving the fish and the birds?

Dr. RIPLEY. I congratulate you, Mr. Brown, because I think you are living in a living laboratory.

Mr. BROWN. I am not sure that congratulations are in order.

I do not have any further questions.

Mr. DADDARIO. Mr. Mosher.

Mr. MOSHER. Mr. Chairman, Dr. Ripley's testimony this morning is very provocative and very demanding and, therefore, very valuable. I am curious about only one detail. On page 5 you say:

> So long as the prohibition against transfers of NSF funds for research in agencies receiving appropriated funds continues in force, the Smithsonian will not receive NSF grants for research projects of individual Smithsonian staff members.

Is that comment in the nature of a criticism or a compliment, Dr. Ripley?

Dr. RIPLEY. No, not at all. It is simply a fact, it is so stated.

Mr. MOSHER. Would it be wise to do away with this prohibition, and whose prohibition is this?

Dr. RIPLEY. This was a prohibition of the Congress.

The Independent Offices Appropriations Act came to this conclusion in 1963.

Mr. MOSHER. This was in the Appropriations Act?

Dr. RIPLEY. Yes. The question came up in connection with the NSF budget, as I recall, before the Appropriations Committee, and the question came up that in view of elimination of possible overlaps, it would be unwise for an agency such as NSF to give grants to individuals within another agency for individual organized research projects, that a member of the Smithsonian's staff embarking on an individual research project which is not budgeted for within the kinds of budgets of the Smithsonian, which merely allow him to hold his position and job there, which he required outside funds of added support for some particular job, that he could not then apply to the NSF for it. We asked for substitute research funds based on an averaging of the last 2 years of the kinds of support that we have been receiving from NSF for original research, and Congress awarded us this sum of money, so that we then have set up, using the NSF as an example, an ad hoc outside panel group to consider applications made by our own scientists for research projects which were beyond their normal salary and budgeting within the Smithsonian.

Mr. MOSHER. And that ad hoc procedure is working fairly well?

Dr. RIPLEY. We have copied exactly the NSF procedure and we are delighted with it because it has I think been an absolutely guaranteed cast iron kind of procedure in which one's own peers are brought in to consider these.

Mr. MOSHER. So you think perhaps the congressional prohibition was wise, at least to your knowledge?

Dr. RIPLEY. After the fact we are perfectly happy about it. We feel we can stand on our own feet, that we do have a reputable and distinguished staff of our own, and when they can go out in a competitive situation in the awarding of grants and receive funds judged on the same kinds of processes, then this is all right. I was concerned at the beginning that, (*a*) we might not receive any research funds through such awarding, and, (*b*) the kinds of procedures which the NSF had set up which were so good might be difficult to achieve in a smaller frame of reference, but I think we have solved it. It is more expensive for us because we have to get the outside panelists and get the people, something that NSF already does.

Mr. MOSHER. No further questions.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Dr. Ripley, I have a question or two on the subject that Mr. Brown brought up, and that is the exchange of scientific and technological information. This is a subject that has continued to pop its head up in our committee hearings ever since I have been on this committee. It is one, I think, of very great importance. As both you and Mr. Brown intimated, there are a number of agencies engaged in that.

The one in the Department of Defense used to be known as ASTIA which I think has changed its name now, there is one in NASA known as STAR. The "S" and "T" standing for "scientific" and "technical" in each. There is quite an effort going on in the Library of Congress in the same realm. Also, private enterprise has put forth a pretty good effort to be a storage house for that information. One of the largest ones is a firm known as Documentation, Inc. I have wondered if the scientific and technical community would not finally come to rest on one or the other of the agencies that I have named as being the one to store information with. In your opinion, are you conversant enough with the other agencies to be able to say that the ball has come to rest on SIE or one of the others?

Dr. RIPLEY. There is a committee known as COSATI, which has to do with the Federal Council for Science and Technology, which I think has been continually examining this problem of science information exchange and its relations to technology, and I would defer to them because they are steeped in this sort of problem. I would be inclined to say that it is probably better to let some of these competing groups, if they are in competition with each other, try their wings and see whether they work or not. I was trying to answer Mr. Brown a little bit along this line but unsuccessfully perhaps. What I really meant was, in a sense I used the phrase, "let the devil take the hindmost," let there be more attempts at this than less, because the problem is one of such urgency, let there be more attempts to collect and interchange information than less, and let them work themselves out.

I do not think that the problem is going to be solved, perhaps, in any other way than by groups trying, either privately or governmentally supported. I would hope that many of the information mechanisms, exchange mechanisms now within agencies related to basic

science and perhaps R. & D., would swing into line and join this group of the SIE supporters. But I would not press for this too hard in terms of the idea that the importance of the total task is such that by attempting to set some limits arbitrarily to the kinds of information exchange experimentation now going on we might damage the information exchange itself.

Mr. DAVIS. It strikes me as being highly desirable that one agency, and perhaps SIE is the logical one, should be thought of as the central storing place. Conceivably, however, it might be possible to link them all together, so if by making an inquiry to SIE you would get the benefit of the facts on hand in the other centers.

Dr. RIPLEY. If this could be done, and I am sure it would be an optimal and utopian situation, if everything could be put on to a coaxial cable, I think everything would be ideal and wonderful. I would be all for it. I would defer to the experts of the COSATI-like committees and adhere to their opinion on the subject.

Mr. DAVIS. That is all.

Mr. DADDARIO. Mr. Roush?

Mr. ROUSH. Mr. Chairman, I merely wanted to ask Dr. Ripley if the social sciences are included in the work of SIE.

Dr. RIPLEY. I believe so.

Mr. ROUSH. Does that include research in the area of criminal behavior?

Dr. RIPLEY. Yes. Would you like me to submit a written answer on the work SIE is doing in the social sciences?

Mr. ROUSH. All right.

(The information referred to is as follows:)

Social and Behavioral Sciences Research Registration Science Information Exchange, July 1965

The Smithsonian Institution's Science Information Exchange (SIE) began in 1949 as a result of Federal agency interest in maintaining a clearinghouse for current research of medical interest from all sources. Since that time the scope of SIE has broadened to include social sciences, as well as the full range of biological and physical sciences, and the Exchange now receives up-to-date information on some 100,000 unclassified proposals, grants, awards, contracts, and projects. Of these, about 70,000 are active research projects, the summaries for which contain detailed information on work in progress or projected. This summary is indexed in whatever depth the description allows by a staff of scientists with backgrounds in the areas covered, allowing retrieval of specific features of interest to the academic and research community.

The focus of coverage remains that of current research activities, and does not include results of research, bibliographies, or reports and reprints from the published literature. SIE supplies information only on demand, concerning studies in progress in specific areas, and issues no regular publications as routine output. Any investigator from a recognized research institution is eligible to ask questions of the system. Some 43,000 requests were processed last year, of which about 5,500 were detailed subject questions. About 1 million notices of research projects were sent out in connection with all types of services.

Input sources for the Exchange include all Federal agencies, State-level programs, research at universities with local support, and major private foundations (about 80). Commercial input to date is limited. Investigators are invited to register on-going research not under support from Federal sources; input in the field of the social sciences is particularly encouraged.

SOCIAL SCIENCES: DEFINITION OF COVERAGE

A compilation of major indexes devoted to the social and behavioral sciences in daily SIE usage has been attached. In the computer tabulation of current research in these areas which has been provided, and in the definitions of index areas which follow, it was not considered useful to distinguish between these two concepts. "Behavioral sciences" as a concept has been broadened in current usage to be fully as comprehensive as "social sciences," including research in the fields of psychology, anthropology, sociology, economics, political science, linguistics, and other areas common to the field usually known as "social sciences." In their applied aspects, behavioral sciences are concerned with practice in such areas as education, mental health, personnel utilization, city planning, communications, and the problems of emerging countries.[1] The Committee on Scientific and Technical Information (COSATI) of the Federal Council on Science and Technology uses a similar grouping of these concepts.[2] In spite of the more biologically oriented aspects of psychology, this field is nevertheless often considered as one of the social sciences.

---

[1] This is the sense in which the concept of behavioral sciences is presented by the behavioral sciences subpanel, life sciences panel, President's Science Advisory Committee, "Strengthening the Behavioral Sciences," Apr. 20, 1962, pp. 1 and 2.

[2] COSATI "Subject Category List, Federal Council on Science and Technology, December 1964."

In the index definitions which follow, the broad basis of definition implied by the previous discussion is utilized. Research in psychology, psychiatry, sociology, anthropology, education, and social welfare is included, along with those aspects of economics, political science, history and law which intersect or overlap either with one of these fields or with the fields of medicine or agriculture. Research in economics, political science, history, or law not related to the other areas named has not been considered as falling within our authorized scope of subject matter coverage. The same type of exclusion applies to topics in the COSATI grouping devoted to the humanities and to administration and management. With respect to documentation and information technology, only the communications-related aspects of this field are covered under social sciences indexes; equipment, instrumentation, and systems research is covered elsewhere. All other groupings included in the COSATI subject list (human factors engineering, linguistics, man-machine relationships, personnel selection, training, and evaluation) are included.

SIE INDEXING OF SOCIAL SCIENCES

Fundamentally, a research project is indexed by the SIE staff to as many subject areas as are necessary to adequately describe the conceptual and detailed subject content of the project. In this respect the field of social sciences is indexed in exactly the same manner as is research in biological and physical sciences. The interdisciplinary nature of current research is such that a problem in endocrinology, mathematics, or chemistry may be an integral part of understanding of behavioral and thus social sciences research. A more detailed discussion of the structure and function of SIE indexes is available upon request.

[Attachment No. 1]

RESEARCH IN SOCIAL AND BEHAVIORAL SCIENCES FISCAL YEAR 1964 AND LATER

Grants are recorded by Science Information Exchange (SIE) for the fiscal year in which the work begins.

The grants listed herein for fiscal year 1965 represent only those that have reached and cleared SIE as of July 28, 1965. All records for a fiscal year do not reach SIE until several months after July 1.

"Continued" refers to grants initiated in previous years and have been renewed or continued as new grants for same research problem.

Current SIE Activities in the Social and Behavioral Sciences

1. GENERAL

In 1964 the Exchange was represented at interagency discussions of the Panel on Behavioral Sciences of the Federal Council on Science and Technology. In the course of a series of meetings, each Federal agency presented a discussion of its general level of support of social science research. There was considerable attention given to delineation of the areas concerned, and it became apparent in the emphasis given to current research in economics that the concepts of behaviorial and social sciences were in effect interchangeable. At that time some of the agencies represented requested computer listings of behavioral science research from the Exchange, but no systematic or comprehensive followup resulted.

Current SIE coverage of Federal agency activities in the social and behavioral sciences has in the past been estimated to be about 95 percent complete. With the advent of multi-million-dollar activity in research and community demonstration projects dealing with poverty, education, and public welfare, it will be necessary to insure that mechanisms for comprehensive registration of these programs are established (see below).

2. PSYCHOLOGY

(*a*) *American Psychological Association*

Discussions have been held with members of the APA staff concerning current research in psychology, and corncerning the nature and extent of coverage of SIE in the field of psychology. A survey was made of the use of the Exchange by psychologists; over 25 percent of life and social sciences requests come from members of the APA.

It is anticipated that an SIE exhibit or a distribution of SIE literature will be included in the 1965 APA Convention arrangements.

(*b*) *New York State Psychological Association*

During 1965 a cooperative program is being undertaken with the New York State Psychological Association which may well serve as a model or prototype for further cooperative efforts with State psychological associations. This association had been collecting research projects in progress being done by its membership; they have undertaken to collect at the same time a description for SIE registration. Many sources of State and local support not now covered by the Exchange should be included in this manner.

3. SOCIOLOGY

At a local meeting of the Columbia Sociological Society in May 1964 it was ascertained that none of the sociologists contacted knew about the existence of the Exchange. Dr. Gresham Sykes, executive officer of the American Sociological Association, was then contacted and a meeting was held July 23. It was agreed that SIE would be represented at the meeting of the American Sociological Association in Montreal (August 31 to September 3) and that a brochure describing SIE would be distributed through the registration desk to all participants. After the meeting another conference was held with Dr. Sykes and it was agreed that SIE undertake a direct mailing to the entire membership of the ASA (8,000) requesting them to register on-going research projects. The mailing campaign was carried out during the months of February and March and resulted in registration of about 200 new non-Federal projects and about 50 subject inquiries. Dr. Norman Kaplan, associate professor of sociology, University of Pennsylvania, whose field is the sociology of science, approached the Exchange with the intent to use the input from the mailing campaign for a number of surveys of the on-going research in the field of sociology.

4. ANTHROPOLOGY

A first conference to explore cooperation between SIE and anthropologists to extend coverage was held on August 12 with Dr. Steven Boggs, executive secretary of the American Anthropological Association, and Dr. Gordon Gibbs, Cultural Anthropology of the Smithsonian Institution. Dr. Boggs expressed interest but said he would prefer to wait for the results of the pilot program wih the ASA. A second meeting was attended by Dr. Boggs and Dr. Sol Tax, editor of "Current Anthropology" in spring 1965. Drs. Boggs and Tax promised to investigate which approach would yield the best results in obtaining registration especially of unfunded or intramural and individual research.

5. MANPOWER

During a conference held January 6, 1965, with Mr. J. Katz and Mr. G. E. Donahue of the Office of Manpower and Automation (OMAT) it was agreed that SIE would be the central clearinghouse for OMAT and that OMAT would make any sources of research in the field of labor automation and its consequences known to SIE.

6. POLITICAL SCIENCES

Dr. W. E. Miller, executive director of the Inter-University Consortium for Political Research, contacted SIE on June 17, 1965, and suggested that political sciences research be included in the coverage of SIE. A computer run showed that about 50 projects involving political scientists are registered with SIE now. Registration of the projects going on at the Inter-University Consortium is being considered now.

7. URBAN RESEARCH

Dr. Scott Keyes, editor of the "Research Digest" issued by the Bureau of Community Planning of the University of Illinois approached SIE in order to obtain all projects on urban and regional planning now registered with SIE. It was agreed to arrange that SIE would register all projects listed in the "Research Digest" which had not been previously incorporated. In September 1964, SIE was proposed as a clearinghouse for urban research and an index was created for this purpose at that time.

8. WELFARE

In November 1964, the Bureau of Family Services of the Welfare Administration, HEW, requested the assistance of the Exchange in a projected publication, "Research and Demonstration Relating to Public Welfare." Inasmuch as the primary requirement was for professional staff assistance in the generation of a subject index to this current research, the Exchange was able to devote the necessary time (about 3 man-months) without charge to the Welfare Administration. This effort was completed in April 1965, and a letter from Mr. Fred H. Steininger, Director, Bureau of Family Services, is attached.

A special index devoted to the coverage of the field of social welfare was generated in August of 1964 in anticipation of the developing Federal interest in this field.

9. OFFICE OF ECONOMIC OPPORTUNITY

Contact has been made (June 1965) with the Office of Economic Opportunity, Office of Research, Plans, Programs, and Evaluation, to arrange for the registration of the newly funded programs of this agency. These programs are now reaching a point at which it is possible to talk in terms of registration of specific projects. There are three types of research and demonstration projects involved: (1) intramural, carried out by personnel of the Office of Economic Opportunity, (2) extramural, consisting of contracts awarded by OEO to external research groups, and (3) delegated programs, consisting of awards to other Federal agencies for the conduct of research and demonstration projects in their particular subject area. Miss Carole McCarthy of this group is attempting to arrange for an SIE notice of research project form to be included and completed with every contract award, and has requested and received a supply of NRP forms for registration of intramural projects. She recommends contact with recipient Federal agencies in the case of delegated programs inasmuch as the several agencies will allot the expenditure of funds for particular projects.

10. OFFICE OF EDUCATION

It is anticipated that large-scale fund expenditure for research will be increasingly available in the Office of Education, partly due to the tie-in with the current interest in positive activities for overcoming poverty. New programs are being funded in the education of handicapped children and in vocational and technical education, and arrangements have been made for this input of research and demonstration projects in these areas. Subject searches are being made on research proposals from the vocational and technical education program.

A development research and demonstration center program of the cooperative research program has been registered through its coordinator, Dr. Ward S. Mason.

The Educational Research Information Center of the Division of Educational Research, under Dr. Harold Haswell, has arranged for close cooperation with the exchange in the registration of research activities; during the past year there was exploration of ways in which the exchange could be of most value to the informational and other programs of the division.

11. OTHER LINES OF ACTIVITY

Contact has been made with the National Council on Crime and Delinquency with respect to their activities in the collection of current research projects in this field. It is possible that projects covered in their publications which are not already registered with the exchange can be registered, and it is anticipated that this contract will be renewed shortly.

Similarly, the Health Information Foundation maintains "An Inventory of Social and Economic Research in Health"; some of these projects are not as yet registered with SIE, and it should be possible to arrange for such registration. This is being pursued.

Finally, the exchange cooperates with various Federal agency information activities not covered above, by providing notices of research projects in the area concerned. An example of this would be the Clearinghouse for Research on Children of the Children's Bureau, Health, Education, and Welfare.

Future Goals of Science Information Exchange (SIE) in Social Science Research

The overall direction of Science Information Exchange (SIE) development should be first toward a comprehensive national inventory of currently active research in basic and applied areas. Since modern research is significantly interdisciplinary, a useful inventory must cover all fields of scientific research, literally from astronomy to zoology.

To cover this broad multidisciplinary spectrum of subject fields on a national scale is, indeed, a formidable task; but only because the collection of timely information from thousands of independent sources is a slow, tedious, and time-consuming process at best. SIE has developed the techniques, methodology, and machinery to do this job. Given time and increasing cooperation from all segments of the scientific community, the job can be done without extraordinary expansion or costs.

The progress toward this goal has lately been most encouraging in the social sciences. For some years our primary target was a comprehensive collection of Federal Government research. We believe that 95 percent of all on-going work in social sciences from these sources is now in hand. For several years the major target has been the private foundations and fundraising agencies that support research in the social sciences. About 80 of the largest are now actively cooperating with SIE and more are being added as fast as SIE manpower and resources can ascertain their identification and engage their participation. However, there are estimated to be 5,000 to 10,000 nonprofit organizations, both large and small, supporting some kind of research throughout the Nation. To identify all of these and to establish smooth-working exchange realtionships with each takes considerable time.

Within the past 2 or 3 years, SIE has also established cooperative arrangements with many State and local government agencies that support or conduct research on some phases of the social sciences. Now that the largest collections, Federal and private foundations, are well in hand SIE will place major emphasis on expanding its collection and services throughout the State and city government agencies.

Other important sources of research information and cooperative exchange are the universities that support and carry out substantial research programs with their own funds, local gifts, grants, and contracts. A number of universities have agreed to participate in the SIE program and we are now redoubling our efforts to reach many more of the hundreds of universities and colleges that are also potential sources.

As noted elsewhere in this report, we have been especially encouraged and have made significant advances toward a comprehensive inventory in social sciences through the interest and cooperation by professional societies, by other associations, and consortia that are primarily concerned with social sciences research.

While SIE is, of course, attempting to advance its coverage on all fronts of basic and applied research, progress in the social sciences, as described above, has been particularly encouraging. On this basis, we would hope to approach a comprehensive national inventory within a few years.

When the approach to this goal is evident, it will be feasible to contemplate the exchange of this kind of information on an international basis.

Scientific research does not recognize international boundaries, and the consideration of an international exchange system advises caution only because of the titanic nature of the task. It would seem reckless to prematurely attempt operations on such a scale without experience, practical techniques, and sound methods that have to be tested and proven on the scale of a national program.

An international exchange system could be practical and feasible at this point, if confined to a reasonable level of effort and scope, and if it were to be approached as a pilot plant test model.

If SIE progress in the social sciences (and in one or two other specialized areas) continues as favorably as it has in the past year, it may soon be the time to consider an international system in a selected area such as the social sciences.

Mr. DADDARIO. Dr. Ripley, you mention the Elliott Committee's endorsement of SIE. Yet, as I recall the Elliott Committee report, it said that the support and use of SIE left something to be desired. Can you give us some idea of what they were referring to in that regard?

Dr. RIPLEY. My impression, Mr. Chairman, was what they were referring to was this matter of input and feedback that I have tried to refer to. As a matter of fact, agencies concerned with information exchange and preparation of reports on current research were not fully prepared to cooperate with the SIE in the beginning. The result of their perhaps reluctance, which may have been for reasons of security and things of that sort, was that as they did not collaborate with the SIE, they saw less and less use for it, it began to drift away from them. This is a very current operation. So as they sort of stood back and were reserved and only gave just partial or token support to the concept, they began to lose track of it, and in this sense it is vitally important that the more one puts in as an agency, the more end use one gets out of the facility. This I think is the nub of this problem. I think that this is being partially solved since the Elliott Committee report came out in greater thrust toward this COSATI overseeing of the agency's activities and attempt to urge more forceably and more strongly all of the participating groups to get into the act, as it were, and start feeding current information in, and the instant they do this, they become quite enthusiastic about it. So it is a process of education, almost missionary-like, going on with some of the cooperating agencies.

Mr. DADDARIO. I regret we do not have more time. We have a quorum call now on the floor of the House.

I wish to apologize to Dr. Bates; I had hoped we could continue. I understand we have an open date, and I hope we might be able to reschedule your testimony, Dr. Bates.

Would you discuss that with Dr. Bates, Mr. Yeager?

We have a whole series of questions, Dr. Ripley, which we like to submit to you so they may be answered for the record.[1] I had wanted you to go into depth on this idea that you have mentioned on page 19, where you said "to preserve him and meet the challenges of constant change."

I think there is more to widening the base and developing knowledge than to just get along in this world, and we quite agree that preserving ourselves, as ominous as that may sound, is something we should keep in mind.

I did hope to get into the idea, too, of having more information about cultures which are escaping us, and some of the animals of this world that are disappearing. I know you have been engaged in the question involving the blue whale. This has a great deal of importance, and I believe that we ought to have more information on these programs. I am sorry we have not had a chance to get into it here, but we can handle it in this other way. We will try to get the questions to you as soon as possible.

I want to thank you for a most informative morning.

The committee will adjourn until Tuesday, next, at 10 o'clock at this same place.

(Whereupon, at 11:35 a.m., the subcommittee was adjourned to reconvene at 10 a.m., Tuesday, July 27, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in Volume II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, JULY 27, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m. in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario, (chairman of the subcommittee), presiding.

Mr. DADDARIO. This meeting will come to order.

Our first witness is Dr. Eric Walker, who is the Chairman of the National Science Board and, therefore, directly involved with the scope of these hearings on the National Science Foundation. Dr. Walker is also the president of the Pennsylvania State University.

We are pleased to have you with us this morning, Dr. Walker.

STATEMENT OF DR. ERIC A. WALKER, CHAIRMAN OF THE NATIONAL SCIENCE BOARD, AND PRESIDENT, PENNSYLVANIA STATE UNIVERSITY

Dr. WALKER. Mr. Chairman and members of the subcommittee, I appreciate this opportunity to appear before you and to comment on three matters concerning the National Science Foundation which I think are of considerable interest. The first is the problem of responsibility and control. The second one is the distribution of funds. And the third one is the engineering problem.

I have read a great deal of the testimony that has been given before this committee, and therefore I will do my best not to repeat what you have already been told.

The first matter I would like to touch upon concerns the question of responsibility and control. I am sure that some of you remember that when the original proposal to create the Foundation was under consideration in the Congress, this matter of responsibility and control was the subject of considerable discussion. When the first bill to establish the Foundation was sent to President Truman in 1947, he vetoed it on the grounds that the organization as then envisaged would be "divorced from the control of the American people," and that neither the Board nor the Director could be held responsible by the President or by Congress for "the determination of vital national policy, the expenditures of large funds, and the administration of important Government functions." And then the act of 1950, under which the Foundation was finally established, was designed to

overcome these objections, and with subsequent modifications, has in my opinion provided a base on which the progress of science and scientific research in this country can be prudently controlled by all parties who should bear responsibility for the proper functioning of such a large and complex enterprise.

The responsibility of the Foundation to the Congress is emphasized through the appropriations, and it is properly maintained by the appropriate budget hearings and hearings such as the one that is being held today before this subcommittee. Responsibility to the administration is effected through the Director of the Foundation, the science adviser to the President, and also through the Bureau of the Budget.

Responsibility to the scientific community is no less important, but it is much more difficult to manage in a clear-cut manner. It is through the Board and through various panels which the Board has created that this area of responsibility must be continually maintained, and the judgments that have to be made in this connection are never made very easily.

The very nature of scientific relationships in this country poses difficulties. As far as the Foundation is concerned, the only practical way to get a competent judgment on the technical value of a research proposal, for example, or on the qualifications of a fellowship grantee, is to rely on the opinions of people who are well versed in the area of science under consideration, or who are qualified by expert knowledge to judge the merits of the individual involved.

This means that we are not infrequently finding ourselves in the position of asking a man to judge the proposal of his friend. The danger inherent in this practice, I think, is pretty obvious. Yet on the other hand we feel it is essential that if the operations of the Foundation are to be wisely managed and the basic goals of the Foundation are to be achieved, this can only be accomplished by having the Board and its panels made up of people who have some acquaintance with scientific matters and some reputation among scientists.

The activities of the Foundation can be effective only if there is a close and strong coupling between the Foundation and the scientific community. The problem is that the Board has a great deal of difficulty making this coupling a useful one.

Changes from time to time in the internal structure of the Foundation, and the several formal reorganization plans, have been aimed, among other things, at strengthening this coupling. The most recent reorganization scheme, which abolished the legal requirement for certain divisional committees, is intended to create greater flexibility in the Foundation's operations as far as the relations with the scientific community are concerned, but whether under the new arrangements the divisional committees will have greater or lesser impact on the operations of the division still remains to be seen.

Now all of this brings me to the major point I want to make in regard to the workings of the Board. The act setting up the Foundation spells out the responsibilities of the Board. In fact, most of the responsibilities for planning, setting policies, and even operations, reside with the Board unless it delegates them to the Director. But I

must emphasize one point: The Board may delegate authority but not responsibility.

The Board, as the Foundation's business has grown, has found it necessary to give the Director authority to fund projects up to certain dollar limits, to continue and expand established programs and to perform other acts in the name of the Board. But the responsibility for the consequences of these decisions still rests with the Board.

Moreover, the Board cannot delegate its responsibility for establishing general plans for the Foundation, deciding in which direction the Foundation should go, and making the larger decisions in which the Director needs the specific support of the Board.

Now all of this takes a great deal of time and effort and it places on the shoulders of the Board a burden which has become much greater as the Foundation has grown from a million-dollar-a-year operation to one approaching half a billion dollars a year.

Now within the past 2 years the Board has reorganized itself to better handle this task. It has established three committees: one dealing with the balance of effort at the present time; one looking toward what ought to be done in the future, say 5 years from now; and one which deals with the current administrative problems of the Board. Each member serves on one of these three committees, which are now meeting on a schedule of approximately 1 day a month. In addition, the members attend the usual Board meetings, which in the past have been held about seven times a year with each meeting being scheduled for 2 or 3 days.

But this isn't enough. There is still too much to do. As the Foundation grows, new ways will have to be found for the Board to maintain its effectiveness in the policymaking functions if it is to keep abreast of the expanding operations.

How this can be done I really don't know, and I must be frank to say that I have not yet discussed this matter with anyone but Board members, and not even the Director. What I am offering here are my own unrefined ideas.

But it seems to me that possibly some of the devices and management methods which are generally used in our large corporations might be applicable to the Foundation. For one thing, I think that the duties of the Board could be more effectively carried out if the Board itself had its own small staff of full-time people—possibly one staff member for each of the Board's committees. These people should be of high enough caliber to be able to put together a policy paper based on informal studies for the committee to discuss for possible recommendation to the Board.

In order to maintain a clear separation between policymaking and operations, which I believe is imperative, these people should not be normally members of the Foundation's staff, closely associated with the operating functions of the Foundation. They must be staff to the Board.

This sort of thing is the practice in many corporations and it might well be effective in helping the Board to keep abreast of its increasingly heavy duties. I feel too that the time is approaching when it might be desirable to have a full-time Chairman of the Board. This might make it possible to have a logical separation between policy-

making and the management of the program of the Foundation, with the Board Chairman being "Mr. Outside" establishing policies, representing the Foundation in the scientific community and among other agencies of the Government, while the Director himself would be "Mr. Inside" with full-time responsibility for the management of the operations.

As you know, this sort of thing, too, is done in industry, where many large corporations have both a full-time chairman of the board and a full-time president. In fact, this pattern now seems to have some acceptance in university circles, for the Massachusetts Institute of Technology now has a full-time chairman and a full-time president.

I might add parenthetically that this might be done quite easily by having the present Director assume the duties as Chairman, and having the Deputy Director run the program.

But certainly something must be done to enable the Board to carry out its policymaking functions more effectively and with greater dispatch. The answer is not clear-cut to me, but perhaps the wisdom of this committee might help in the solution of the situation.

Mr. DADDARIO. Dr. Walker, you referred to the fact that the Board has given up some of its authority but not its responsibility over the course of time. Therefore it has worked back to the point where the Director carries a greater load. Is it your feeling that during this period of time that the type of recommendation, which you now are making, might have been a better solution than to have removed from the Board some of its authority and responsibilities which it originally had?

How do you see this whole process?

Dr. WALKER. I really don't see it clearly, Mr. Chairman, because the growth of the Board, the Foundation, and its responsibilities and the amount of money it has had to spend, has been a gradual one, from $250,000, or whatever it was, to now almost $500 million a year. I do not think you could ever put your finger on a point to say this is where a great change ought to have been made.

Every year the Board has found it necessary to delegate more and more responsibility to the Director. If we didn't do this, things wouldn't get done. I feel the burden on the Director's shoulders must almost be unbearable, and somewhere or other I think he has had to get some help in doing these things.

Let me say I have not talked this over with the Director, but I am confident this is true.

Mr. DADDARIO. It might be helpful if you could give us some idea of how the workload of the Board grew to the point where it was not able to function as it should—you used the words, I think: "This is not enough." When did the burden begin bothering you to the point that you began thinking about how the Board might fulfill its function in a more proper way?

Dr. WALKER. Mr. Chairman, you must remember I have been on the Board just over 4 years, and when I came on the Board I was convinced that there were more things to be known than I could learn about. But if you look at the history of the Board, you see that in the early days the only thing they had to do was to grant fellowships and basic research contracts. Then we started adding such things as the science information job, which you will hear about later, the in-house

laboratories, the educational development programs, and so on. The work of the Board has grown almost like an inverted pyramid, and sometime in this growth I think it became impossible for the Board to follow everything, certainly to follow anything in great detail.

I do not think we have really examined the responsibilities and the capabilities of a part-time Board such as this.

Mr. DADDARIO. You indicate that the formation of a staff of this kind would present an opportunity to have additional staff help for the Board, separate and apart really from the help that is given to you now by the Director through his staff. If this burden has grown, so far as the Board is concerned, then the burden has also grown on the Director. From that point down through the whole National Science Foundation these stresses and strains must be considered as a problem in the performance of the functions which are intended for the National Science Foundation.

I get the feeling, as you mention your recommendations, that this is something about which this committee ought to be considering and concerned.

Dr. WALKER. Let me say, Mr. Chairman, that I have a firm conviction, and perhaps a prejudice, that when a company or an organization gets to be above a certain size, which I think the National Science Foundation has now passed, that you must have a clear-cut separation between policymaking and operations. I think that the Board ought to turn its attention solely to policymaking, and that whoever is running the show ought to be clearly responsible for the operations. I know this is not well spelled out, and I am unable, in this short time, to offer any good suggestions as to how it can be spelled out, but I think it ought to be.

Mr. DADDARIO. Under the reorganization plan, will this new arrangement involving the divisional committees have greater or lesser impact on the NSF's operations. Do you have some concern about it?

Dr. WALKER. I have some concern about it, sir, because I think the divisional committees are one of the couplings that the Board has with the scientific community. Yet I fail to see how the Board has armed itself to take advantage of the recommendations and the knowledge of these divisional committees. I would hope that if we did have a full-time staff that we could use them in trying to grind the opinions, hopes, and recommendations of the divisional committees into the actions of the Board.

Mr. DADDARIO. Then you see no particular conflict that might arise as a result of the formation of such a Board staff, in contrast to the work being done by the Director and his staff?

Dr. WALKER. Well, this always poses difficulty. There is always the problem of the people in the head office interfering with the people who are running the show, whether it is in a university or in a large industry. But I think the proposal I suggest has been proven in the past, sir. You would have to tell the staff to keep their noses out of the operations, and that their problem was finding out about helping to set policy.

I think this can be done.

There is also the problem that if you have a full-time director and a full-time chairman of the board, they would have to be compatible people. This is one of the reasons I made the suggestion I did, because I think the two people I mentioned are compatible people and can get along under a working arrangement like this.

Mr. BROWN. Mr. Chairman?

Mr. DADDARIO. Yes?

Mr. BROWN. Can I ask a question or two along that same line?

Mr. DADDARIO. Certainly.

Mr. BROWN. Is your point that in order to make the change which you are suggesting and establish a small staff for the Board, that this requires legislative action? Is this outside the powers of the President?

Dr. WALKER. I couldn't answer that question, sir. I don't believe it does require legislative action, but I do not know.

Mr. BROWN. It seems to me that it should be within the powers of the Board if in its wisdom it feels it needs a staff that it should establish a secretariat to the Board which could be insulated to whatever degree may be necessary from operations. It is fairly common for boards to have this kind of staff for their own purposes. I would think, subject to review by legal analysts, that this would be feasible to do at such time the Board itself feels it is desirable.

I am concerned about the emphasis which you place upon the separation of policy and operations. Of course, it is the function of the Board to establish policy, but it is impossible to completely separate policy functions and operations because, after all, the policy relates to the operations. It is necessary for you to be fully informed as to the operations in order to properly develop policy.

Dr. WALKER. You cannot completely separate the two, but you don't want to establish policy in terms of today's problems. You want to establish policy in terms of long-run problems. I think this is why industry usually finds it desirable to have a staff to set the general policies of the corporation, separate from the people who are running the show.

Mr. BROWN. Yes; this is true, but I think if we were to ask the Director, I would suspect that somewhere in the Director's staff he would have a group concerned with long-range policy and rather divorced from current operations. Again, this is typical of progressive managements. They all have this kind of staff available, to the degree which the Board desires it, the resources of a policy planning staff separate from operations could and should be made available to it at the present time.

Dr. WALKER. Yes, Mr. Brown; this does exist. There is a planning staff in the Board's staff, under the Director. I think the problem, as I see it, is that there is not close enough coupling between this staff and the Board proper, and this may be the Board's fault.

Mr. BROWN. Yes; this is something that we need to be informed of as a committee, and which the Board, itself, needs to continue to analyze, I am sure.

No further questions.

Mr. DADDARIO. Will you proceed, please, Dr. Walker?

Dr. WALKER. One of the problems which I know this committee has been concerned about, and one of the problems which the Foundation faces is the uneven distribution of funds granted by the Foundation and their apparent concentration, I say "apparent" concentration, in a few colleges in New England and on the west coast. I have little to add on this problem. We are all aware of the situation. I think some of us deplore it. But the reasons for it are really very complex, and I think there is no simple answer to it. In my opinion, one of the main causes of this condition can be found in a kind of spiraling situation which has no beginning and no end but has as part of it the simple fact that the schools that pay the highest salaries to their faculties are the ones that get the most Federal business. One has only to look at the information published by the Office of Education to verify that fact. By paying the highest salaries they get the best people. Having the best people, they put in the best proposals. These proposals have a higher percentage of acceptance by the Federal agencies that grant the funds. And so these schools get a higher percentage of the grants that are awarded, and at a higher price. And since the price is high, they can continue to pay higher salaries, attract better people, and continue to submit the best proposals.

I know of no simple cure for this situation. It is very difficult and I think quite undesirable to try to fight excellence. This is a case where it is hard to weed out the fault without eradicating the virtue.

On the other hand, of course, we are conscious of the need for more widespread distribution of support for research and for the fuller development of the Nation's potential for scientific activity. Yet, even here, we must not forget that it is from the institutions which are presently the strongest that the men must come who can lead the way in the improvement of the others.

In the meantime, however, in order to accelerate the process, the Foundation has undertaken several programs designed to help correct this situation, which I might repeat to you here.

The first of these are the science initiation grants, which provide support for promising young people who are starting off in colleges where there is relatively little research being conducted.

Another is the institutional grant program, under which the colleges and the universities are granted funds beyond those made available for special-purpose programs—funds which the institution may use flexibly to blend and balance its activities and to strengthen its weak spots. The amount of these funds which an institution may receive is determined by a tapered formula which favors the small school that does not have very many special-purpose grants.

The third program, the science development program, is especially designed to increase the number of colleges of recognized excellence in research and education through the broad and quick upgrading of selected schools and universities, those which show a potential for real improvement. Such schools may apply for relatively large unrestricted grants which may be used to strengthen a single science activity, a group of related activities, or the entire science program of the institution.

Through these three programs, we hope to be able to broaden the distribution of funds awarded and provide more balanced support among

the Nation's campuses. The only other way I could think of to do this would be to put a top limit on the percentage of a university's funds which could come from the Federal Government. I would not advocate such a step under present circumstances, but unless over a period of years the situation starts to correct itself under the current regulations and practices, certainly some new rules would be in order.

I would like to make a few comments about the NSF and engineering. In order to be able to speak frankly, I would like to remove my hat as the Chairman of the National Science Board and to resume my former one as the president of the Engineers' Joint Council.

A good many engineers have felt for some time that engineering has not received proper recognition from the National Science Foundation. There are some of us who remember that during the forming days of the Foundation we tried to have it called the National Research and Engineering Foundation. We were eventually willing to settle for the word "science" when we were assured by definition it would include engineering. But it is pretty clear that engineering, although it has been accepted as a member of the family, has been in some respects treated as kind of a stepsister to the basic sciences.

I think there is some lack of understanding of the true nature of engineering in any government, and indeed in engineering educational circles. I would sum it up by saying that engineering is not analysis; it is synthesis. Engineering is not the accumulation of new knowledge, but it is the process of using knowledge together with money, manpower, and materials to produce instruments which satisfy human needs. And in this process, trial devices and systems must be built and tested. In our economy the engineering process works very well as long as someone can make a profit out of the device or system that is being created and sold. Television sets, washing machines, and airplanes get engineered. But there are many devices and systems the country needs where there is no immediate dollar profit and where no single industry, and certainly no single company has a major interest. This is where, in my opinion, the Federal Government might finance and support the necessary engineering design and test, and such test programs are going to be very expensive.

Mr. MILLER. Doctor, could you give us an example of one of these programs?

Dr. WALKER. I am going to give you some. If I don't give you a good one——

Mr. MILLER. I am very much interested in this, as you know.

Dr. WALKER. There are people who say that all of the engineering required for eventual production can and should be done on paper, after the basic research has been done—without recourse to the test of trial models. But let me point out this is not the way things are best done—or usually done—in other fields.

We have theoretical physicists who work on the theory of high energy physics and who predict with pencil and paper just what will happen when so and so is done. But when they have completed their predictions, they feel compelled to build a high energy accelerator in order to determine if what they predicted really does occur. And we are willing to spend 10 or many more million dollars on such an accelerator. Yet there are many practical needs in society today which could be filled by engineering systems and devices, and for some reason we

seem to be unwilling to spend anything like this amount in designing them and subsequently building engineering models for test purposes.

It seems to me a little incongruous in this day of technology to have a postman visit your house or your office once or twice a day to deliver your mail, when it might be done more efficiently somewhat the same way we deliver gas or electricity. But who can design and test a new system like this? And what about the transportation problem? Who is going to design and test the new systems by which we move from the home to the office and back to the home again?

Let me take as an example the important problem of water retrieval. This is one of the problems on which proposals have already been made, asking the Federal Government to finance new systems. In an area of this sort, of course, a great deal can be done with pencil and paper. But there are questions here that require experimental engineering.

We all know that our streams are becoming polluted, that the detergents we use and wash down the drain are producing certain nutrients in the water that grow vegetation which chokes the streams with weeds. We also know that this effluent is an excellent fertilizer and it can perhaps be sprayed on our fields—as a way of getting rid of it, as a way of improving our crops, and as a way of recovering the water. But if one starts a program using this effluent for fertilizer, there are many things to worry about. What are the effects going to be on the insect population, and on the wildlife? Is it really going to fertilize the land, or poison it? What is going to happen as the water seeps down through the ground? How far will it have to seep before the detergents are broken up, chemically broken up? What happens when the downcoming water hits the water table? Will it provide a proper source for recharging the ground water supplies? And so on.

Obviously the testing out of a system like this is a large-scale engineering project. The proposal for such a project was once submitted to the National Science Foundation and was considered as not being basic research. Of course, it isn't the kind of research we are accustomed to support in physics, chemistry, math, and so on. I might say if I had been on the staff, I would have turned it down as a proposal to the National Science Foundation. Yet, it seems to me this is a most fundamental and useful type of research. And if it is, where in the country is it going to be supported? The Department of Commerce? The Department of Interior? The National Institutes of Health? Or where?

Mr. Chairman, it seems to me there are many large engineering projects which need to have research done on them and which need to be put into shape so that cities, municipalities, States, and even the Federal Government can use them and the people can profit by them. It seems to me that the National Science Foundation might well use some of the Federal funds with which it is entrusted to support such projects. This is a policy decision which might need specific congressional approval. The question should be posed and the answer should be given.

All of this returns me to my original point. There is much work for the Board of the Foundation, and I am not certain the Board is equipped to do this work.

Thank you, Mr. Chairman.

Mr. DADDARIO. Do you have a question along that line, Mr. Chairman?

Mr. MILLER. I think the doctor answered the questions I had in mind.

I want to congratulate you on this, because it is something this committee is concerned with, and we hope to start some hearings on this very shortly, under Mr. Daddario, in the next phase of his work.

I believe that here is where we are completely missing the opportunity to serve the future, and one that we must fulfill. I could point out to you that 17,000 acres of very fertile land in the San Joaquin Valley in California have been so saturated with chemical fertilizers and pesticides that it practically has to be taken out of use. This is a resource we can't lose.

I could go on with some other examples that have come about, the fact that the pesticides that are used on boll weevil in the Mississippi Valley also have a great affinity for the shell fish in the Gulf of Mexico. How do you balance these out? How do we correct them?

With the population burden that the future holds, if we don't start looking at these things now, it will be too late not too many years from now.

Thank you.

Mr. DADDARIO. Mr. Mosher?

Mr. MOSHER. Dr. Walker, what about the present size of the Board, itself? Should it be larger or smaller?

Dr. WALKER. I don't think it has any real impact, Mr. Mosher. Let me say the Board members do work hard, and most of them—by "most" I mean 21 out of 24—attend the meetings regularly. But how a part-time group can get hold of these problems and do the job with which it is charged is something I don't see clearly.

Mr. MOSHER. Is it 25 members?

Dr. WALKER. Twenty-five, counting the Director, as a member.

Mr. MOSHER. If each one had a full-time staff person, that would be quite a large policymaking staff.

Dr. WALKER. Oh, yes.

Mr. DADDARIO. You were not talking about each member having a staff. You were talking about it in relationship to size, weren't you?

Dr. WALKER. I was talking about each committee. There are three committees.

Mr. MOSHER. I got the impression that each member would have one.

Dr. WALKER. I hope not, sir.

Mr. MOSHER. That seemed a little large.

Dr. WALKER. I might say, Mr. Daddario, I make these suggestions mostly because I am discontented with the operations of the Board. I don't feel we are doing as good a job as we should do, and in making these suggestions I am simply throwing them out, hoping that with your wisdom and other people's wisdom, perhaps we can come up with a solution to this, which I think is a most important problem facing the country.

Mr. DADDARIO. We recognize it in that vein, Dr. Walker. We are appreciative of the suggestions and the fact that it does give us an opportunity to measure and match them in accordance with what has been said by other witnesses, and what we see the National Science Foundation doing.

Mr. Roush.

Mr. ROUSH. Dr. Walker, I have been very much aware of the fact that the Board is conscious of the need of an equitable distribution of research funds. I think the Foundation has done an excellent job in the distribution of its own funds. I have wondered, however, if it couldn't do a better job in leading the way and stressing to other governmental agencies the need for distribution of their research and development funds.

Is there a definite relationship between the excellence of institutions located in a certain area and the distribution of Federal research funds, particularly that which goes to industry?

Dr. WALKER. I think that is two questions, Mr. Roush. First, we are talking about the distribution of Federal funds to the universities. I would say that there are even more compelling reasons for, let's say, the Department of Defense to pick out the best universities because the people in the Department of Defense are trying to get the most for the Government's money. If you want to get the most for your money, you go to where the best people are. Then, obviously, industry tends to settle around the good universities. They can use the university staffs for consulting purposes; they can get the graduate students; it is the climate in which this kind of person wants to live; and I think you can point to numerous examples where industry has gone to where the good universities are.

Mr. ROUSH. What has the Foundation done in response to the 1960 report of the President's Scientific Advisory Committee, which advocated additional centers of academic excellence?

Dr. WALKER. Well, it has started on the program which I did mention of trying to pick out a group of schools that have the potential for becoming first class, and grant them large grants of money, hoping to move them up from where they are to being first-class universities. This program has just gotten off the ground, but I have high hopes for it, and it is moving very fast. Ten grants have already been made.

The results of this will be some 5 years in coming, but I think the Foundation has moved very fast on this.

Mr. ROUSH. Now back to my first question, and reversing it, does the distribution of research funds to industry by any of the many governmental agencies affect the distribution of funds to institutions on the part of the Foundation? In other words, in developing centers of excellence, are you in any way persuaded by the existence of research and development in a certain area?

Dr. WALKER. I don't think so, sir.

Mr. ROUSH. Does the granting of funds and the distribution of funds to industry for research and development affect the development of institutions of excellence in a certain area other than the activity of the Foundation?

Dr. WALKER. It would be quite indirect if the giving of funds to industry helps a university in the neighborhood of that industry. The industry might ask some of the university people to conduct some of the research under a DOD program or something like that, and there would be some effect in this direction, but I don't think a great deal, sir.

Mr. ROUSH. Does the growing imbalance in the distribution of Federal research funds to industry in any way endanger present and existing centers of excellence insofar as our institutions are concerned?

Dr. WALKER. No. I don't think it does because I think that the excellent universities are so strong that things like this really cannot affect them.

Mr. ROUSH. I would take issue with you on this point. It seems to me that you stress the fact that people tend to migrate where we have centers of excellence. There is an endangering of institutions in the Midwest. We lose 90 percent of the graduates of Purdue University to places other than the Midwest. If this imbalance should continue to grow, we would endanger the excellence of the universities in my section of the country or any section of the country which is described in terms of research funds as a poor section of the country.

Dr. WALKER. Yes, now you have mentioned Purdue as your school.

Mr. ROUSH. It is not my school. Indiana University is my school, but Purdue is in my State.

Dr. WALKER. As you know, there is considerable concern about the doctoral degree holders from these schools leaving that section of the country, and I suppose it could work in the reverse way. People might say, "Well, no one stays there; therefore, why go there for a graduate degree?"

This could happen. I think I defended myself by saying "indirect reasons."

Mr. ROUSH. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Dr. Walker, I was just trying to apply your statements to my own part of the coutry. I happen to be from Georgia. The fact that Harvard or MIT might be progressing I don't believe means, at least in the Southeast, that we are retrogressing.

Our schools are growing very rapidly, the student body and the number of doctorate degrees are increasing every year, and it just occurs to me that progress in the centers may not mean retrogression in the hinterlands.

Do you think that is possible?

Dr. WALKER. I think it is not only possible, it is very true, sir, that education is going ahead so fast these days that in the words of the Red Queen "You have to run as fast as you can to stay where you are." I think we all find ourselves in this position.

Mr. DAVIS. I want to thank you for a very enlightening and stimulating statement. I want to say that having a liberal arts background rather than a technical background, it has been a source of considerable curiosity to me to try to find the line that separates science from engineering. Your statement was a great help to me this morning on that particular question.

Mr. MILLER. Would the gentleman yield to me?

Mr. DAVIS. Certainly.

Mr. MILLER. Doctor, he stresses this point that he has a liberal arts background. He is a lawyer by profession and an astronomer by avocation.

Dr. WALKER. That would almost make him an engineer.

Mr. DAVIS. I am a rank amateur, but very interested in that subject.

Mr. DADDARIO. You may as well add, Mr. Miller, he is also a Member of Congress.

Mr. MILLER. And he has been a judge.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Doctor, I am interested in the composition of the board as to its balance between the various scientific and engineering fields. I have a list of the members here in front of me, but I am not sufficiently acquainted with their backgrounds to know.

Could you give us an indication of how you feel the board is constituted in terms of its balance as between the physical sciences, the health sciences, the social sciences, and engineering? Could you give us also your general feeling as to the adequacy of the board in fulfilling the role of communication or coupling between the scientific community and the Foundation?

Dr. WALKER. Well, I don't think the balance between the disciplines you have mentioned was at all designed, but my feeling is it is very good. The members of the board, whether they are in the social sciences or physical sciences or in engineering, do communicate with each other very well, and I would be hard pressed most of the time to say whether or not a physicist or engineer or a social scientist was talking in the board meetings.

I think each member speaks up as we get into the area of his particular competence, but my general feeling is the distribution is just about right.

Mr. BROWN. Well, I think that is a very good statement for a chairman of that Board. I have been harping on the subject of the resources devoted to the social sciences by the Foundation, and looking at the membership of the Board I see only one person that I can really identify as a person definitely in the social sciences.

I want to ask your comment on the general problem here as to, first, do you feel that the Foundation has a positive responsibility to support basic research in the social sciences? Do you feel that the efforts in that line are adequate if you feel there is a positive responsibility? And do you feel that the voice of the social scientists is adequately represented by the one member that I positively identify and others that you may know about on the Board at the present time?

Dr. WALKER. My own personal feeling, Mr. Brown, is that the Board has been very timid about this, that we had our roots in the physical sciences—physics, chemistry, astronomy and so on—and that we were very timid about getting into engineering, and also timid about getting into the social sciences because these are not as comfortable to us as physics.

I think this is one of the things that the Board now ought to speak out on, and I think we now have a guideline. If we are going to have a Foundation for the arts and a Foundation for the humanities, then obviously I think the National Science Foundation ought to say that the social sciences are really part of our field of influence. And this is one of the problems that the Board ought to turn its attention to.

Mr. Brown. I am aware that the Board is concerned with this problem. Obviously its actions have indicated this in establishing committees to study it and a division within the organization.

I think the concern of this committee and my own is really how far do we go; which is the proper policy role, and obviously there is no present answer to this. We are seeking such an answer.

You are familiar with the work of the Office of Naval Research, for example. It is my understanding that this Office supports at least some research in the social sciences.

Dr. Walker. That is correct.

Mr. Brown. Now they seem to have no embarrassment about this to my knowledge. Could you comment on that?

Dr. Walker. Yes. Many of the Navy's problems have been in the area of the social sciences—for instance, the problem of just getting a crew to live together in a submarine which stays underwater for 30 days. I think the Office of Naval Research properly recognized this as a problem for the Navy and thus recommended some research in the social sciences.

Mr. Brown. They have also had a number of projects in somewhat broader fields of personnel and human management, as I recall, which I think have general applicability in any large-scale organization. The question is whether the Navy is perhaps the best organization to do this.

Another example from recent newspaper reports of research being done in foreign countries by the DOD are Project Camelot and a similar project in Brazil. This is basic research in the social sciences. The policy framework, in which these have been authorized, is apparently not clear.

They apparently went into them mainly because DOD could get money, and a more appropriate agency could not. This is the reason I think this question does need exploration at the present time.

Leaving that subject for a moment, I want to go into this matter of your remarks with your other hat on, the Engineer's Council. You have touched on some things which, as Chairman Miller indicated, are extremely significant from the standpoint of the progress of our society. Is it not true in a very real sense that a large part of the problems which face this country today in terms of a better adaptation to its environment are engineering problems?

Dr. Walker. I think so.

Mr. Brown. Are you suggesting that the National Science Foundation is the place in which effort should be made to solve these problems? For example, the ones that you gave, a national communications system improvement program in the Post Office, a national transportation improvement program, a national water reclamation program, major engineering projects all requiring the relating of science to the needs of our people.

Does it seem to you that the National Science Foundation should be taking the lead in these areas?

Dr. Walker. This is a policy decision, I think, in which the Congress as well as the Board of the Foundation and the administration have to share. My feeling would be that the National Science Foundation could do this and probably should do it, but wiser men might say there is another avenue to do it.

Mr. BROWN. The real problem, it seems to me—and I ask for your comment on this—is that the Congress itself has not decided that these are problems to which it should address itself. Would you feel that this is a correct statement?

Dr. WALKER. Yes. My observation would be that Congress has not decided that they are problems, and in the cases where they have, there has really been no clear-cut decision as to whether the work should be done.

Mr. DADDARIO. Would you yield there for a moment, Mr. Brown?

Mr. BROWN. Certainly.

Mr. DADDARIO. You have touched on one point which inhibits a better performance in areas where there is no profit out of a device or a system. You are actually recommending that through the National Science Foundation the research could be done which would demonstrate the feasibility to perform certain of these programs. Then I would imagine that you would decide whether to do it through the private sector or through the Federal Government or through a combination of the two such as the Communications Satellite Corp.

Dr. WALKER. That is precisely it.

Mr. MILLER. Will the gentleman yield?

Mr. BROWN. Yes.

Mr. MILLER. Doesn't it come down to this, one of the points you wish to make, and I will cite two instances in my own State, frankly affecting my own district, where the cities and counties around San Francisco Bay have bound together and set up a political entity for a rapid transit system. They voted $800 million worth of bonds to start with.

Then the Federal Government made a grant to develop a rapid transit system, and now they are in the process of trying out new types of equipment. However, the grant from the Federal Government doesn't come from the National Science Foundation, though they are dealing in an engineering problem, it comes from Housing and Home Finance.

Dr. WALKER. That is right.

Mr. MILLER. Correspondingly, in the port of Oakland a man, who operates the helicopters in the San Francisco Bay area, who is a good entrepreneur, and who is willing to take a chance, decided to try hovercraft in this area. This area is the first place where hovercraft will be put into public operation in the United States. It will start next month. But again when he wanted to get Federal aid, it is from the Housing and Home Finance Agency, which has no capability in the field of engineering.

As a matter of fact, when we wanted to bring these craft out, there was a question as to which agency do they fall under, and who is going to regulate them.

So the ICC, the CAB, and the Maritime Administration had a meeting. One said: Are they trucks? Another said: Are they airplanes? And another one said: Are they ships? Someone said they were ships. Then the Jones Act was in our hair. We had to go to DOD to sign a declaration saying they were interested in the operation because we had to buy these ships from an English firm. They will be manufactured in this country under a patent, but to get them now we had to buy them in England.

The point I want to make is that the Federal money going into this thing is coming from the Housing and Home Finance Agency. I have no fight with that. My complaint is, What have we done in the field of hovercraft or in the field of rail transportation to modernize and bring it up to date?

Certainly the railroads aren't going to spend money to do it. They should, but they are not. Are we going to sit back and be strangled by poor transportation because we don't spend money to examine and probe it? Now we are going to do a lot of things between here and Boston. I think the last program is to dig a great subway between Washington and Boston. Maybe that will come in a few hundred years. What are we going to do about the near future? How are you going to get down from Hartford to New York?

Dr. WALKER. You have got me, Mr. Chairman. I have a problem in that regard.

Mr. DAVIS. Will the gentleman yield to me?

Mr. BROWN. Yes.

Mr. DAVIS. Dr. Walker, I want to make the observation that some very powerful human factors enter into this question. As Dr. Holloman of the Commerce Department pointed out when he testified before our committee, every department tends to fund its own science. For instance, the Post Office Department has studies involving computers. The Department of Agriculture has its own. This is true all the way across the board.

It is a fact that it is just literally impossible to hem up science, and each person who has a job to do naturally wonders if there isn't some help to be had at the hands of science, and so he takes part of his money and spends it on science.

I think if you did try to say that all the science of communications or of transportation should be relegated to this, that, or the other agency, you would find that you just simply can't trap science that way. You couldn't keep, for example, the Department of Commerce from using some of its money for the science or the engineering of transportation. I think the human factors in there are something really to be reckoned with.

Dr. WALKER. We find this in universities, sir. You have a department of electrical engineering, and pretty soon they are doing physics and mechanical engineering, and you can't stop it.

Mr. BROWN. We have some very fundamental philosophical problems involved in this discussion, the one that Mr. Davis raises about containing science in any one organization, or engineering. The other problem raised with regard to the support of activities which may be construed as being in the private enterprise sector, and the considerable fear that exists that Government funding in these areas means Government control and a step in the direction of a socialistic type of government. We really need to have a great deal more confidence in our dedication to the free enterprise-private property system, and with the recognition we may be enhancing that system through the proper expenditure of funds to solve some of these problems.

For example, in the space program as a whole we have recognized that private enterprise is not the proper vehicle to explore the Moon or Mars, and yet private enterprise has benefited tremendously from

the Government efforts in this area. I hope it will continue to benefit, just as I think it would benefit if we were to undertake a national program concerned with the development of a good transportation system or a good water conservation system.

I think this would be a shot in the arm for our whole economy. But as long as there is a fear that the Government movement in this direction is a step toward socialism, and this is worse than the Devil itself, we are not likely to make much progress in this area.

I have no further questions, Mr. Chairman.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. No questions.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I regret to say that other activities, which I didn't expect would occur, kept me from being here earlier. I was most interested in your statement. However, I think since both you, representing the Board, and Dr. Haworth are here, I should say one thing has been very clear to me from the last several weeks of these hearings. There have been extremely few serious criticisms of the National Science Foundation per se, or of the Board or its operations, and that in general what has come out has been to the Foundation's favor rather than to its detriment. I think it is well to take note of this in passing.

We have learned a great deal more about the other agencies that the Foundation deals with rather than about the operations of the National Science Foundation itself, and interaction between these, where I think a great deal of difficulty may lie.

I have asked a number of persons this question: What is the relationship of the Board to the Director, and what is its responsibility and authority? You said on page 2:

The Board may delegate authority but not responsibility * * * in deciding which way the Foundation must go.

As far as I can determine, the Director reports to both the Board and the President, and I haven't quite understood who does what, and what role, for example, the President's science adviser has in terms of the policies established by the Board.

For example, let us suppose the matter of transportation should come up, and let's say the Board felt that the expansion of effort on hovercraft may be desirable. At this point suppose the Board were to vote 3 to 2 that there should be an additional $10 million spent in the area of hovercraft. Now, what inhibitions would you have in making such a decision as a Board?

Dr. WALKER. Thankfully, this situation has never arisen since I have been on the Board where we have had an unresolved disagreement. But the Board does approve the request for an appropriation, and I suppose if we did meet an impasse like this, the Board could insist that a line item be made in the request to the Bureau of the Budget and the Congress that something be done about hovercraft.

Mr. VIVIAN. I am not referring so much now to a dispute between the Director and the Board. I am speaking of a dispute between yourselves and the Budget Bureau and the President's Office. Let us say you wanted more money spent on these methods of transportation which seem to be halfway between sea, land, and air, but never on one of them, and let us say there is objection, for example, from the

other departments that are involved because they want to be leading lights in this expansion. You make a decision—and I will even give you a unanimous decision on the part of the Board—that you should do something.

What happens now if you should run into some objections from the other agencies? Just how does this get resolved? As the act reads, it says the Board has the authority and responsibility for the National Science Foundation. Therefore, you can recommend to Congress anything that you see fit.

Dr. WALKER. I suspect this would be resolved at the President's Office level, before it ever got into the Congress.

Mr. VIVIAN. In other words, the Foundation's Board does not really desire to have the authority to exercise its prerogatives according to law?

Dr. WALKER. Speaking for myself, I don't see how we could.

Mr. VIVIAN. How are the Budget Bureau requests processed? When you come up with a suggested budget for the following year, this request, I presume, is reviewed by the Board and passed on by the Director to the Bureau of the Budget. Has the Bureau of the Budget turned down significant items or requests?

Dr. WALKER. I couldn't answer this question. You would have to ask the Director that.

Mr. VIVIAN. Have they been?

Dr. HAWORTH. Yes, they have.

Mr. VIVIAN. Have these amounts been significant fractions of the year's budget?

Dr. HAWORTH. I don't think you can single out any one item and say it has been a significant fraction. There have been items. Of course, the amounts for the various items are subject to the Bureau's approval and negotiations between the Bureau and the Director and so on. But there has been initiation of new programs that have been turned down or postponed.

Mr. VIVIAN. Can you give me some idea whether those programs that have been turned down have been those which the Board and yourself felt should be started, for instance, in new areas and which were cut off for budgetary reasons or which were cut off for what I will call conflict-of-agency reasons?

Dr. HAWORTH. I don't think of any, Mr. Vivian, that have been other than for financial reasons.

Mr. VIVIAN. Strictly financial?

Dr. HAWORTH. Yes. Remember my experience is very limited. I have been here only 2 years.

Mr. VIVIAN. Perhaps I should ask Mr. Walker, in his experience, which is slightly longer in this regard.

Dr. WALKER. I don't recall any that have been turned down for conflict of agency. We often get turned down on amounts that we want for specific programs.

Mr. VIVIAN. For example, following up on Chairman Miller's comments, suppose you concluded that the transportation system needed an influx of new ideas and you put in a request to the Bureau of the Budget. Do you anticipate that it wouldn't be turned down because of funds?

Dr. WALKER. I think as to the one you have chosen, you would get into quite a hassle whether we or Commerce did it.

Mr. VIVIAN. This question has come up many times.

I feel the Board's position is not a very thoroughly defined one even though it has been very successful in its functions. I think the words in the statutes don't have much relationship to the facts of life.

Dr. WALKER. I don't think the Board has ever exercised its authority nor its responsibility to really search out areas which need to be investigated and then point them out as areas that are neglected. This isn't an easy thing to do, and the work of the Board, as you know, has been growing very fast, and new jobs are presented to it so often, that it is kept busy with this sort of thing. Instead of innovating, it has been filling needs.

Mr. VIVIAN. I have felt for some time that the Board's role with reference to the overall scientific interest of the Nation is basically prescribed by two things. The first is that it really in a sense cannot dispute with the President on major expenditures, and I agree that it would be nonsensical. Second, the Board represents principally the universities and institutes of the Nation rather than principally the overall scientific community of the Nation.

Recommendations had to be viewed from what I will call the recommendations of the university community in a broad sense.

Dr. WALKER. That is correct.

Mr. VIVIAN. Therefore, when you run across places where private industry is very heavily involved, such as transportation, you immediately come into a conflict of who is carrying the ball. Yet I wonder if that is desirable because I think many of us feel that some of the most desirable directions of activity, are being slowed down by lack of assurance that if you progress in this direction, you wouldn't be chopped to bits.

I am trying to find examples of where you have tried to progress and have not been chopped to bits perhaps, but have had a few gouges taken out. Where have been the battles you lost?

Dr. WALKER. These are difficult for me to give you because we haven't grabbed the ball and run with it sometimes when I think we should have done it.

Mr. VIVIAN. There is an old saying which goes to Members of Congress, if you win by more than 55 percent, say 60 percent of the constituents, you have made a mistake because you haven't disagreed with people often enough.

I wonder if the same thing doesn't apply to the Board, and perhaps the National Science Foundation in total, perhaps you should have lost a few fights.

Dr. WALKER. I wouldn't disagree with you, sir.

Mr. VIVIAN. I will stop there.

Mr. MILLER. You are ahead now.

Mr. DADDARIO. Dr. Walker, I hope we might be able to send a series of questions to you. Obviously there are many more questions that we could ask than we are permitted by time.[1]

We appreciate your coming and grateful for your assistance. Thank you.

Dr. WALKER. Thank you, sir.

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

Mr. DADDARIO. Our next witness is Mr. William T. Knox, who is with the Office of Science and Technology in the Executive Office of the President.

I have had occasion to know Mr. Knox over a period of time. He was with the Esso Research & Engineering Co., from which he is now on a sort of a sabbatical leave working with the Government, and I think his biographical sketch in regard to that should be of interest.

His job is to assume responsibility for stimulating development of more effective scientific and technical information systems, which includes a great deal of research management. This is a subject which the committee has heard a great deal about, Mr. Knox, and we are pleased you are with us this morning.

Mr. DAVIS. Mr. Chairman, if I may interpose this comment, I also noted from his biographical sketch that he is a fellow son of the State of Georgia. I want to particularly welcome him here before this committee.

I think you are only the second witness that I have had occasion to listen to who is from my own State. We are all happy to have you.

STATEMENT OF WILLIAM T. KNOX, CHAIRMAN, COMMITTEE ON SCIENTIFIC AND TECHNICAL INFORMATION OF THE FEDERAL COUNCIL FOR SCIENCE AND TECHNOLOGY; ACCOMPANIED BY COL. ANDREW A. AINES, EXECUTIVE SECRETARY, COMMITTEE ON SCIENTIFIC AND TECHNICAL INFORMATION, FEDERAL COUNCIL FOR SCIENCE AND TECHNOLOGY

Mr. KNOX. Mr. Chairman, could I ask Colonel Aines, who is executive secretary of COSATI, to join me?

Mr. DADDARIO. Certainly.

Mr. KNOX. I want to say to the members of the subcommittee I am glad to appear here today as it makes a comprehensive review of the National Science Foundation. As the chairman has said, the area that I am to deal with is that very large and ill-defined complex of activities known as scientific and technical information activities. To put it a little more accurately, it is the systems by which information is transfered in order to promote the progress of science and technology. Another way of characterizing this is to talk about the systems that support science and technology.

I mention these because they call attention to the main concern, which is the progress of science and technology. Too often there has appeared to be an emphasis on scientific and technical information systems and problems within themselves—without relating them to the cause and the reason for their existence, which is the progress of science and technology.

President Kennedy focused on the real issue when he said in 1963:

> One of the major opportunities for enhancing the effectiveness of our national scientific and technical effort, and the efficiency of Government management of research and development lies in the improvement of our ability to communicate information about current research efforts and the results of past efforts. Strong science and technology is a national necessity and adequate communication is a prerequisite for strong science and technology.

May I also mention another overemphasis in recent years. Too often there have been repetitions of fascinating falsehoods about the inadequacies of the present system. One such myth was traced recently by Dr. Oettinger of Harvard. The myth, which you may have heard yourselves, was the fact that 5 years and $250,000 were allegedly spent in the United States to needlessly duplicate a result published in the Soviet Union in 1950 and that solutions to important military problems were delayed by those 5 years. Dr. Oettinger painstakingly discovered that—

the trivial results in question were surprisingly well known to all specialists most concerned, in at least one instance as early as 1937.

Dr. Oettinger further states that—

It is therefore entirely out of the question that anyone would knowingly have spent $200,000 on this matter or that any important project would have been hurt by a delay in the discovery of the article.

I recognize that a modern, healthy, information system is as vital to the health of the overall scientific and technological programs of this country as a healthy circulation system is vital to a healthy human being. I could even say, just as a healthy transportation system is vital to our economy, too.

However, although there are many specific aspects of our present information system which we know could be considerably improved, I feel that steps for improvement must be based on well-reasoned, analytic studies of the total needs, consideration of several alternate possible solutions, much thought about costs and controls and future trends, and a number of large-scale experiments.

This brings me to some of the things that Dr. Walker was talking about, about our need for an organized engineering systems approach. This is certainly another area in which this would be profitable. In this field we have the same type of organizing and financing problems, too, within the Federal Establishment, which the committee just discussed with respect to how to get things accomplished in transportation systems or our water systems.

My role is that of chairman of one of the committees of the Federal Council for Science and Technology; namely, the Committee on Scientific and Technical Information. With your indulgence, I will refer to this committee henceforth as COSATI, a nickname or acronym now known throughout the Nation in information circles.

I would like also to pay tribute at this point to the individual members of COSATI, who are very able, dedicated people, and who feel a keen compulsion to work together for the common interest.

Let me stop saying this big mouthful of "scientific and technical information," and henceforth, when I refer to "information," you will know I refer to scientific and technical information.

In addition to my chairing COSATI, I serve Dr. Donald Hornig, Director of the Office of Science and Technology, as technical assistant for information activities.

The relationship of the National Science Foundation to information activities was covered in detail in the report entitled, "The National Science Foundation—A General Review of Its First 15 Years," prepared by the Science Policy Research Division of the Legislative

Reference Service. In addition, both Dr. Haworth and Dr. Hornig have referred to the Foundation's activities in this area in their testimony given earlier. I do not plan, therefore, to discuss, except in very general terms, the Foundation's relation to the Federal Government's overall program in information.

Rather, as your letter of invitation suggested, I shall present for your information, as you review the Foundation's activities and plans, some of the highlights of the total governmental programs in information as seen from COSATI and the Office of Science and Technology.

Let me first outline the scope of COSATI's concerns. As you can imagine, they are very broad, since they are related to all the scientific and engineering disciplines and to all of technology. As you can also imagine, since COSATI has existed for only 3 years, there are many problems still waiting solutions. Under the recent chairmanship of Lt. Gen. William J. Ely, U.S. Army, and continuing under my leadership, the substructure of COSATI is being reorganized into eight panels. The panels already in being are as follows:

OPERATIONAL TECHNIQUES AND SYSTEMS

This panel is concerned with: acquisition, accession, in libraries, abstracting, indexing, announcement, distribution, terminology control, equipment compatibility and convertibility, wholesale and retail resources, specialized information centers, libraries, and depositories. This is a big order. This is our "workhorse" panel, charged with improving the quality of performance and coordination of current and near future Federal agency programs.

INFORMATION SCIENCES TECHNOLOGY

The missions assigned to this panel are to make recommendations for the orderly development of information sciences technology by avoiding unnecessary duplication of agency R. & D. efforts and by identifying gaps in agency R. & D. programs; and the orderly transition from current to improved systems.

EDUCATION AND TRAINING

This panel helps us look for improved education and training of information specialists, and means for increasing their supply, which is a very short supply. It will also help educate scientists and engineers and managers in the use of information resources and system.

We are considering other panels at present.

INTERNATIONAL ACTIVITIES

This country needs information produced by scientists and engineers in other countries. In these days of plans for computerized information systems serving an international community, it is important to have a panel to help coordinate Federal agency activities; to set standards for systems, to recommend international exchange policy and procedure, and to improve the many translation programs carried on in and out of Government.

INFORMATION GENERATION

This will include such areas as reporting techniques, input quality control, technical writing, meetings and symposia, and the large area of security, proprietary, and copyright matters. In a word, it is concerned with the beginning of the information cycle.

INFORMATION USERS

As the name implies, this panel will be concerned with users and their needs for information and data; also, with steps to be taken to let users know the information resources that exist, and how to get to them.

EXTERNAL RELATIONSHIPS

The Government is a big factor, but not the only factor in the information business. Industry, the universities, trade associations, and technical and professional societies have a considerable stake in science and technology, and the information systems serving it. This panel will be charged with the responsibility of safeguarding their interests.

BUDGET AND STATISTICS

The panel will help with budget reviews and analyses of agency information programs, by developing commonly agreed upon and useful statistics.

COSATI's concerns thus embrace not only systems actually used to transfer documents and information from one user to another, but also embrace the initial publication processes and the producer of information, the user groups with their varying information needs, and the education and training of information systems operators and the producer-user groups in the use of modern information systems. Not only is there a large service function here, but information systems also have their own large research and development program.

The size of the Federal Government's information program is not easy to determine. This is basically because it is difficult to make a distinction between some information activities and the research or engineering activities of which they are an integral and essential part. To all scientists and engineers, information transfer is an inseparable part of their science and engineering. One study of the work habits of chemists has shown that research chemists spend as much as one-half their time in communicating.

. Mr. DADDARIO. Mr. Knox, will you provide, for the record, the membership of COSATI, and the panels?

Mr. KNOX. I will be glad to do so, sir.

(The information requested is as follows:)

FEDERAL COUNCIL FOR SCIENCE AND TECHNOLOGY, COMMITTEE ON SCIENTIFIC AND TECHNICAL INFORMATION

Chairman: William T. Knox, Office of Science and Technology, Executive Office of the President.

Executive Secretary: Col. Andrew A. Aines, U.S. Army, Office of Science and Technology, Executive Office of the President. (22421)

MEMBERS

Dr. Burton W. Adkinson, Head, Office of Science Information Services, National Science Foundation. (Alternate): Henry J. Dubester, Deputy Head, Science Information Coordination Section, OSIS, National Science Foundation.

W. Buril Barclay (RD-67), Chief, Domestic Coordination Staff Systems R. & D. Service, Federal Aviation Agency. (Alternate): ——— ———, Chief, Library Services Division, Federal Aviation Agency.

Edward J. Brunenkant, Director, Division of Technical Information, Atomic Energy Commission. (Alternate): John Sherrod, Assistant Director for System Development, Division of Technical Information, Atomic Energy Commission.

Walter M. Carlson, Director of Technical Information, Office of Director of Defense Research and Engineering. (Alternate): Dr. Robert B. Stegmaier, Jr., Administrator, Defense Documentation Center.

Melvin Day, Director, Office of Scientific and Technical Information, National Aeronautics and Space Administration. (Alternate): Paul Feinstein, assistant to Director, Office of Scientific and Technical Information, National Aeronautics and Space Administration.

H. H. Eckles, assistant to the science adviser, Department of the Interior. (Alternate): Leslie Scattergood, Chief, Branch of Reports, Department of the Interior.

Foster E. Mohrhardt, Director, National Agricultural Library, Department of Agriculture. (Alternate): Dr. Harold C. Knoblauch, Associate Administrator, Cooperative State Research Service, Department of Agriculture.

William H. Mills, Office of International Scientific Affairs, Department of State. (Alternate): Curtis L. Fritz, Chairman, Foreign Affairs Information Management Effort (FAIME), Department of State.

Dr. Donald A. Schon, Director, Institute for Applied Technology, National Bureau of Standards. (Alternate): Bernard Fry, Director, Clearinghouse for Federal Scientific and Technical Information.

Dr. William H. Stewart, assistant to the special assistant to the Secretary (health and medical affairs), Department of Health, Education, and Welfare. (Alternate): Dr. F. Ellis Kelsey, special assistant to the Surgeon General (science information), U.S. Public Health Service.

Dr. Benjamin B. Wells, Assistant Chief, Medical Director for Research and Education in Medicine, Department of Medicine and Surgery, Veterans' Administration. (Alternate): Frank R. Smardak, Coordinator, Scientific Information, Department of Medicine and Surgery, Veterans' Administration.

J. Lee Westrate, Office of Management and Organization, Bureau of the Budget, Executive Office Building.

OBSERVERS

John K. Vance, Central Intelligence Agency.

Dr. David Z. Robinson, Office of Science and Technology, Executive Office of the President.

Edward E. Harriman, Office of Research and Engineering, Post Office Department.

G. W. Seymour, Chief, Research and Development, Small Business Administration.

Herbert Turner, Agency for International Development (TCR). (Alternate): Erwin Lachman, Chief, Science Information Unit, Office of Research and Analysis, Agency for International Development.

LIAISON

Dr. Dwight E. Gray, Chief, Science and Technology Division, Library of Congress.

Dr. Theodore W. Taylor, Assistant to the Secretary, the Smithsonian Institution. (Alternate): Dr. Monroe Freeman.

PANEL ON EDUCATION AND TRAINING

John Sherrod, Assistant Director for Systems Development, Division of Technical Information, Atomic Energy Commission (Chairman).

Charles M. Gottschalk, Office of Assistant Director for Systems Development, Division of Technical Information, Atomic Energy Commission (Secretary).

Joseph Becker, Central Intelligence Agency.

Dr. Frank L. Schick, Assistant Director, Library Services Branch, Office of Education, Department of Health, Education, and Welfare.
Miss M. Joan Callanan, professional assistant, advanced science education, Division of Graduate Education in Science, National Science Foundation.
Edward K. Grimes, Special Projects Office (AFRSTS), Directorate of Science and Technology, Headquarters, U.S. Air Force.
Kirby B. Payne, Assistant Director, Field and Special Services, National Agricultural Library.

PANEL ON INFORMATION SCIENCES TECHNOLOGY

Dr. Ruth Davis, Office, Director of Defense Research and Engineering (Chairman).
Dr. Harold Wooster, Office, Director of Defense Research and Engineering.
Charles J. Austin, National Library of Medicine.
Mr. Curtis L. Fritz, Chief, Foreign Affairs Information Management Effort, Department of State.
Dr. Joel O'Connor, data processing officer, Division of Technical Information Extension, Atomic Energy Commission, Oak Ridge Operations Office.
Van A. Wente, Chief, Documentation Branch, Scientific and Technical Information Division, National Aeronautics and Space Administration.
Richard See, program director, information systems program, Office of Science Information Service, National Science Foundation.
Miss Mary Stevens, National Bureau of Standards.
Dr. Bruce Waxman, Research Grants Review Branch, Division of Research Facilities and Resources, National Institutes of Health.
Dr. Richard Wilcox, Office of Naval Research, Department of the Navy.

PANEL ON OPERATIONAL TECHNIQUES AND SYSTEMS

Dr. Armen G. Abdian, Defense Documentation Center, Defense Supply Agency (Chairman).
Budd C. Moyer, Defense Documentation Center, Defense Supply Agency (Secretary).
Gerald W. Beveridge, Chief, Technical information Division.
John Forbes, Chief, Division of Indexing and Documentation, National Agricultural Library.
Paul C. Janaske, Clearinghouse for Federal Scientific and Technical Information.
Eugene P. Kennedy, Library Services Division (HQ600), Federal Aviation Agency.
Hubert Sauter, Chief, Technical Services Branch, Scientific & Technical Information Division, National Aeronautics & Space Administration.
Robert L. Shannon, Assistant Director, Division of Technical Information Extension, Oak Ridge Operations Office, Atomic Energy Commission.
Seymour I. Taine, program director, Federal science information program, Science Information Coordination Section, Office of Science Information Service, National Science Foundation.

Mr. KNOX. Recognizing the difficulties in separating information services from other aspects of research and development, COSATI has developed some very rough budget estimates for information programs of executive branch agencies for fiscal year 1966, as follows:

Colonel Aines shows these rough estimates on this chart (fig. 1).

Science-technology information activities

	Millions [1]
Publication and distribution	$130
Bibliographic and reference service	80
R. & D. information sciences and systems	60
Symposia and technical meetings	40
Information centers	20
Management and training	20
Audio and visual media	10
Budget issues	10
Translations	5
Support publications	5
Total, estimated	380

[1] Numbers rounded. Estimated obligations, not expenditures.

FIGURE 1

First of all, I want to note we have rounded the numbers, and they are estimated obligations, not expenditures.

The largest single item is for publication and distribution—this refers to the vast amount of published material that is turned out by individual Federal agencies—reporting results of scientific and technical programs. It also covers the cost of distributing this material.

Bibliographic and reference services refer to such things as abstracts and other bulletins. The Atomic Energy Commission turns out Nuclear Science Abstracts, for example. This category also refers to agency library services, and things like that.

You will notice about $60 million a year is going into research and development in the technology that is applicable to information transfer. A lot of this is in the military.

Symposia and technical meetings——

Mr. DADDARIO. There will be three bells.

Mr. KNOX. We feel like ringing a bell on the symposia and technical meetings, too, sir, because they account for about $40 million of these estimated obligations.

Information centers, that is, special centers operating on one subject aspect of science and technology, are shown at about $20 million. The remainder of the categories become progressively smaller, about $5 million on translations and $1 million on actual subsidy of scientific and engineering journals published by nonprofit, non-Government organizations.

Mr. DADDARIO. Also, if it is possible to break down for the record the agencies involved in the expenditures of these funds——

Mr. KNOX. It would be extremely difficult, Mr. Chairman. The estimates here are not consistent, agency to agency. Estimates account for a substantial part of the total dollars which we are showing here, and because of the interrelation of the actual research effort itself with these dollars we talk about here, I think it would be practically—well, it could be misleading, and I am not sure it would be very meaningful.

Mr. DADDARIO. Why don't we leave that go at the moment and see if it is necessary.

Mr. KNOX. All right.

Mr. DAVIS. May I ask a question, Mr. Chairman?

Mr. DADDARIO. Yes.

Mr. DAVIS. You say this is the information programs of executive branch agencies. I take it that includes departments?

Mr. KNOX. Yes, sir.

Mr. DAVIS. The whole executive branch?

Mr. KNOX. The whole executive branch.

Mr. DAVIS. What sort of definition did you use for what would amount to an item of scientific and technical information?

Mr. KNOX. These categories are the ones that we tried to solicit estimates from the agencies on, for example, how much money they were actually spending to print documents.

There is a very large, for example, printing establishment down at Oak Ridge, run by the Atomic Energy's Division of Technical Information.

Mr. DAVIS. Suppose someone ordered an almanac? Would you consider that as a piece of information that would be added to that total?

Mr. KNOX. The categories were restricted to information that was rather easily construed as being in the fields of science and technology, in support of the research programs either within the Federal Government, or supported by the Federal Government, outside.

Mr. DAVIS. I see. It had to be in support of some research program?

Mr. KNOX. Or the results of some research program. That is right.

Mr. BROWN. Mr. Chairman?

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. Could we clarify that just a little bit more by indicating some examples of what this does not include? For example, this does not include public relations activities of the various agencies, I presume?

Mr. KNOX. This is correct. It would not include, for example, the actual experimental procedures, themselves, the actual laboratory work or the actual hardware costs, or the actual procurement of the items.

Mr. BROWN. But in the information field, there is a great deal of publication that does not deal with science and technology?

Mr. KNOX. This is correct. This has nothing to do with the agencies' public information program, as an example.

Mr. BROWN. Thank you.

Mr. KNOX. The part that is played by the National Science Foundation in these information programs is highlighted by this following chart (fig. 2.)

Sci-Tech information activities (comparison of NSF and total Federal agency programs, fiscal 1966)

[In millions of dollars] [1]

Function	NSF	Total
Translations	2.4	5
Information centers (SIE, NRC)	3.6	20
R. & D. in information sciences and systems	5.1	60
Other functions	7.3	295
Total, estimated	18.4	380

[1] Numbers rounded. Estimated obligations, not expenditures.

FIGURE 2

It is a summary presentation to call attention to the primary activities of NSF in this field. You will notice in the translation category the Foundation has obligated about half the total obligated by the executive branch, \$2.4 out of \$5 million. This is in support of translations of foreign language scientific and technical materials. It also operates the Science Information Exchange, or has the management responsibility for the Science Information Exchange, and the National Referral Center for Science and Technology, which are two components of the national network. For those two activities it has budgeted \$3.6 million out of a total of \$20 million. It spends about 8 percent of the total spent by the executive branch for research and development in information sciences and systems. This is less than the 12 percent, on the average, of basic research support, that the Foundation gives relative to the total Federal support for basic research.

Dr. HAWORTH. I think, if I may interrupt, I think the 12 percent refers to our support of academic research. As to total research, it is far less than that.

Mr. KNOX. Overall, NSF supplies about 4.5 percent of the total Federal agency funds for information activities. This low value is due in large measure to NSF not having large in-house information systems, as do many of the other Federal agencies.

Let me turn now to some of the more general problems facing the Federal Government and look at them through the eyes of COSATI.

Since COSATI is a committee of the Federal Council for Science and Technology, its main functions have paralleled those of the Council. In its field of information, COSATI has served as a means for:

1. Identifying problems of concern to more than one agency;
2. Developing an interagency consensus for steps to ameliorate or eliminate the problems; and
3. Exchanging information among Federal agencies.

In the last 3 years, as a result of COSATI's studies and recommendations, a number of actions have been taken by Federal agencies to improve information systems. Some of these are:

1. A uniform policy to guide Federal agencies on financial help to nonprofit, nongovernmental scientific publications. This is the so-called page charge policy, whereby Federal agencies pay, if requested by the publisher, certain costs of publication.
2. A standard for microforms of technical reports. We call these "microfiche,"—if you haven't seen what a "microfiche" is, I thought you would like to see one. Colonel Aines has a sample. We look for this new standard to create a new, large market, and thus lower unit costs.
3. A uniform method for identifying Federal reports. This is called descriptive cataloging, and the technique is of particular help to those people who have to store and retrieve reports.
4. Finally, a subject category list to be used throughout the Federal Government for the announcement of reports.

This will make it easier for Federal report users to locate information. I have copies of these standards here if you would like to take a look at them later, or now.

These COSATI actions do not have the glamor of a spacewalk, but they are very significant actions in bringing about better coordination of Federal and non-Federal information activities. We will have to follow their implementation, and modify and correct them when necessary. We are also working hard on other standards and policies.

In addition to this kind of action whereby individual agencies and non-Government organizations have been enabled to make their own information systems more effective and/or more efficient as components of the total national network, COSATI has been the mechanism by which, or with whose endorsement several new organizations have been created to carry out special functions of the national network. These new central organizations are:

1. The Clearinghouse for Federal Scientific and Technical Information, operated by the Department of Commerce, which is primarily a technical reports dissemination agency.
2. The Science Information Exchange, which this committee, I believe, is familiar with, operated by the National Science Foundation

and the Smithsonian Institution, which is perhaps better called the Federal Research Project Registry.

3. The National Referral Center for Science and Technology, operated by the National Science Foundation through the Library of Congress, which is an inventory of who knows what in science and technology in the country, and is also a device for referring people to those resources.

4. The National Standard Reference Data System, operated by the Department of Commerce and designed to provide this country with critically evaluated compilations of numerical data, very essential for engineering work.

Now, in another kind of activity, as Dr. Hornig mentioned in his testimony before this committee, about 6 months ago, following several suggestions from committees of the Congress that the executive branch exercise stronger, more aggressive leadership in this area, an interdepartmental COSATI task group began a top-level planning effort. This effort is focused on developing the conceptual framework for a plan for improvement of the overall complex of scientific and technical information activities in the United States. Congressional committees playing a leading role in this area have been the House Committee on Science and Astronautics, the House Select Committee on Government Research, an Ad Hoc Subcommittee of the House Committee on Education and Labor, and the Subcommittee on Government Reorganization of the Senate Committee on Government Operations.

In order to develop the conceptual framework in a realistic fashion, it was necessary to consider also the activities outside the Federal Establishment, since the non-Federal and Federal activities are mutually dependent on one another, and large sums of Federal funds go directly or indirectly in support of these activities. Very early in the deliberations of the COSATI task group the importance of continuing dialogs with representatives of the various components of the complex of information systems was recognized. Within the Federal Government there is a readymade mechanism; namely, COSATI, present. But for non-Federal scientific and technical information activities there is no such mechanism. We have, accordingly, participated in a number of special meetings held to present the task group's preliminary thinking regarding a concept toward which the information systems in the United States could develop. These meetings have already been held with top level representatives of scientific and engineering professional societies, industrial and trade associations, the technical and business press, and library groups.

Although there are many other areas of interest, the task group has focused its efforts so far on formalized communication mechanisms, primarily document-handling mechanisms. The group is being assisted by a study team from the System Development Corp. As a first result of this cooperative effort, I hopefully anticipate a report to be issued this fall. The functions and relations of major components of the document-handling system, such as abstracting, indexing, and alerting services, are being studied. Another major area of interest is the impact of advanced technologies on the information transfer network.

What have we developed so far? First, we have concluded that the farflung, widespread nature of the information system can be roughly conceived as in part analogous to the telephone network, which is a mechanism for connecting people who want to know or to talk, with other people who either have the desired information or who are willing to listen. It is a mechanism completely at the service of its users, and it demands only an elementary knowledge to be able to use it. The telephone system operates on a real-time basis, however, and this is a big difference from information systems, which in part transfer knowledge acquired some years ago to today's users.

In order partly to recognize this difference in user need, and partially because of the different functions and different types of staff involved, we have, in our preliminary thinking, divided the body of the national network of information systems into two parts. These parts will be a complex of library systems (document-oriented, such as traditional libraries), and a complex of information evaluation and retrieval systems (information-oriented).

There seem to be necessary several libraries at the national level, handling documents in such fields as medicine, agriculture, engineering, earth sciences, physical sciences, behavioral sciences, et cetera.

I am not saying they have to be separate entities, but these subject areas appear to be desirable.

Each of these libraries would be concerned with acquiring all the pertinent literature in its field, cataloging or indexing it, announcing the availability of the literature, and providing copies, if requested. These would be structured, operated, and administered in somewhat similar manners. Perhaps each library would be responsible to a Federal agency with primary mission responsibilities in it field of interest, such as the National Library of Medicine which reponds to the mission of the Department of Health, Education, and Welfare. Coordination and compatibility among the libraries would be a primary goal really from the beginning, and a question for early decision would be the mechanism for bringing about this coordination.

Because of the size of our population, and the diversity of demands made on libraries for documents, ranging from help to the teenage student to the needs of the lay adult to the needs of small and large business and the professions, the rest of the library network will be essentially retailers of documents. Other library systems (Federal, college, and university, public, specialized, industry, institutes, schools, et cetera), would, as now, look to the national libraries for loan of documents, catalogs, et cetera, as may be appropriate, and would, in turn, provide some of the input to those libraries. But their main role would be to serve those users who will be satisfied with documents.

The other part of the system—the complex of evaluation and retrieval systems—would consist of those activities of Government agencies, universities, industries, and societies (professional, scientific, and trade) that are concerned with providing information, as opposed to documents, to specific audiences directly concerned with science and technology, namely, the scientists and engineers themselves, and managers of scientists and engineers. The elements of this system would be expected to:

1. Provides secondary current awareness, such as abstracts bulletins;

2. Analyze and evaluate information; not only the information contained in documents, but that information just developed and still unpublished;

3. Facilitate searching of the literature through deep indexing and other means; and

4. Retrieve specific information on request; i.e., answer on-the-spot questions.

These activities are normally much more closely identified with the research and development programs and the scientific and engineering disciplines than are the document-oriented activities centered on libraries. They require scientific and technical orientation and competence of the participating personnel. Here, too, there needs to be an improved mechanism for really bringing about the desired coordination of effort.

Such, then, are the things that COSATI has done, is doing and will do in the future. We look forward to continued progress in interagency coordination, and to increasingly productive cooperation with the nongovernmental community.

I have highlighted COSATI's development of standards and of uniform practices and procedures. COSATI has also helped create several new governmental organizations which filled obvious gaps in the national information network. COSATI and OST are now planning to help bring about a more effective and efficient national network.

There are some difficult problems to be solved. For example, the advent of national computer-based information systems will raise new issues. Because of the Federal Government's deep involvement in the national effort in science and technology, and because of its close relation to and financial support of the extensive nongovernmental activities in so much of the information network, the Congress will ultimately have to decide what parts of the evolving modern information network and to what degree these parts are appropriately Federal Government responsibilities, and appropriately private enterprise responsibilities. As the report of the President's Science Advisory Committee said:

> Government involvement in scientific communication is going to grow. Can this growth be so guided that user-sensitive non-Government systems are not swamped by elaborate Government systems?

Other difficult problems are the sources and mechanisms for financial support for the information network.

Federal agency information services are usually subsidized by the general taxpaying public for the benefit of the users of the service. This is sometimes justified on the grounds of eliminating the costs of billing and collection of charges for many small items; sometimes on the grounds that more use is encouraged if the services are provided free; sometimes because it is judged to be for the general welfare. It is common experience that people generally associate value with cost to them, and in most cases people are willing to pay for something they really need.

In the absence of a cost-controlling mechanism, an information service like other services, is likely to become unwieldy and cumbersome and unresponsive to user needs. Such a situation could lead to overemphasis on the production or processing side, and to under-

emphasis on the true needs of the user, which is the marketing side. A mechanism by which the users of an information service are made to pay a substantial fraction of the costs for the service is a valuable control device. It also acts as a spur to the information service managers.

There are other serious problems, too, such as the lack of adequate skilled manpower to man the modernized information network, and the lack of adequate information facilities on our college and university campuses, where the future users of the system are being trained.

But the one problem demanding our greatest attention at present is the problem of creating a permanent mechanism for insuring the effective and efficient management of the vast, far-flung, almost incredibly complicated series of functions which together make up the national information network.

As Dr. Hornig testified earlier, such a permanent mechanism probably must be outside of the Office of Science and Technology, as presently conceived.

There are a number of mechanisms which have been proposed in the past few years by people, both in and out of the Federal Government. Let me mention a few possibilities for a central management mechanism. These are: a Comsat-like corporation deeply involved in the actual operation of the information network, with both governmental and private interests; a new Federal agency managing all agency scientific-technical functions, much as the General Services Administration handles other services; a new Federal agency restricted to top-level planning and evaluation, with existing agencies continuing to manage their internal information systems; the assignment of top-level planning and evaluation functions to an existing Federal agency; or a continuation of the present multifaceted management.

These possibilities, and others, are now being examined closely by the COSATI task group and the System Development Corp. I hope that we will have some solutions to this problem within the next few months.

Mr. DADDARIO. Could you go into the relationship of NSF to this entire problem of information? Where does it fit in? How does it fit in with COSATI and OST? What are the lines of communication that exist with relation to it performing its functions with regard to the providing of information?

Mr. KNOX. First, NSF is a member of COSATI. It also operates, as you well know, the Office of Science Information Service.

Mr. DADDARIO. What is its membership?

Mr. KNOX. It is one of the members or COSATI. We can show you who the other members are. There are 10 agencies who are members of COSATI, and NSF is a member like other agencies, just as the AEC, DOD, HEW, and other departments and agencies are members. It has no preferred status on COSATI, if that was a question that you were raising.

In the short time that I have observed at close range, the operations of the Federal information systems, I have certainly been impressed

by the effectiveness of those information systems which are directly related to the mission of the agency or department. I have already referred to the National Library of Medicine. There are other agency systems that are also oriented to that agency mission, such as the Defense Documentation Center, the National Library of Agriculture, and the information programs of NASA and the AEC. If—it is an "iffy" question—if one were to carry this analogy into the National Science Foundation, one might describe an appropriate information mission for the NSF somewhat like this: To insure modern, healthy information systems required to support basic research and education in sciences and engineering.

In other words, tie the information requirements closely to the other missions of the Foundation. This need not be NSF's only information mission.

Mr. DADDARIO. Let me put it this way: Back in 1958, PSAC in their report called for the creation of a unified, efficient, and comprehensive scientific information service with NSF playing a coordinating role.

In a January 1959 letter, in an Executive order, the President asked NSF to assume responsibility for a Federal coordinating plan.

Does the transfer of the coordinating activity to OST in 1964 and the present OST leadership, as you have explained it, today reflect a lesser role for NSF? I think you have already indicated that it does have a lesser role in just being one of the members.

Shouldn't it have a more important function because it does perform a basic research and education function, and, of course, information transfer from that point on does become important?

Mr. KNOX. If I might just comment, or refer back to the testimony, one of the possibilities that is certainly under consideration would be the assignment to an existing Federal agency of increased responsibilities in the top-level planning and coordination of this complex of information systems. The Science Foundation would certainly be a candidate, and a very serious candidate—contender, let's say—for that kind of responsibility.

Mr. DADDARIO. What you have said indicates that the National Science Foundation was a very prominent member in the Government's activities, insofar as information is concerned, then slipped from there to being just one of the members on the Committee on Scientific and Technical Information, and now it is envisaged as being one of the agencies that might be considered. So it has gone a long way from being an important part of this kind of an operation.

I wonder if this is good or bad?

Mr. KNOX. Mr. Chairman, I don't know that NSF has, in fact, slipped, as you have described it, along this path. The Office of Science and Information Service was brought into being by the Congress at a time when the agencies such as AEC and the Department of Defense had very large ongoing information programs, spending tens of millions of dollars a year on them. Asking a sister agency to coordinate, to evaluate, and to plan the activities and information programs of these other agencies, when it had no established competence in the field, was asking it to perform a very difficult task. The reassignment of the overall Federal Government coordinating role in this area to OST, in connection with the Reorganization Plan No. 2 in 1962, was in recognition of the difficulties that might have

been expected in asking a sister agency to coordinate very large on-going information programs of the other agencies.

Mr. DADDARIO. But not impossible?

Mr. DAVIS. If the gentleman would yield?

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. It reminds me the job that GSA took over, when GSA decided to attend to the housekeeping needs of most all the other Government agencies. Wouldn't you say it has a parallel there? It may not be very close, but it was a similar problem.

Mr. KNOX. We are talking, I believe, in the information systems area, about an operating problem, an on-going operation, which is different, I believe, in type and in degree, from the other substantive programs of the Foundation, which are basic research and the support of education and engineering.

NSF, at the time OSIS was created, was not a very large agency and it was not in effect a competitive operating agency with these other sister agencies.

Mr. DADDARIO. It is the assumption because they were small, they were incapable of doing it?

Mr. KNOX. No. I did not mean to say that.

Mr. DADDARIO. The question comes up as to why should they not have been given that particular opportunity. We can go into that.

Mr. Vivian, do you have one quick question?

Mr. VIVIAN. I have a brief observation.

I would gather that OST did not have a large staff trained in information systems at the time it was not given to NSF because it did not have a large staff trained in the activities.

Mr. KNOX. OST was not in existence at the time.

Mr. VIVIAN. That could not have been the reason for it, per se.

Mr. DAVIS. May I ask a short statement of what the Systems Development Corp. is?

Mr. KNOX. It is one of these nonprofit think factories. I will be glad to supply you with some information.

(The information referred to is as follows:)

Systems Development Corp. is a nonprofit corporation which has specialized in information and data processing and in training for advanced technological systems. Although most of its work has been with the Department of Defense it has also served a number of organizations in the Federal Government and some State and local governments. Last year it served over 100 different government customers and did about $50 million worth of business. SDC has had a quite extensive research and advanced development program in information processing, computer programing systems, and natural language handling.

Mr. DADDARIO. Mr. Knox, we will submit additional questions to you.[1]

If it is at all possible, we will arrange for you to come back here some time before these hearings are closed. This is a very important subject in which you are involved, and you are in an excellent position to give us your views because of your involvement with this in the private sector and in your present capacity.

I want to thank you and Colonel Aines for coming.

This committee will adjourn until tomorrow morning, at the same place, at 10 o'clock.

(Whereupon, at 12:20 p.m., the subcommittee was adjourned to reconvene at 10 a.m., Wednesday, July 28, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

WEDNESDAY, JULY 28, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee), presiding.

Mr. DADDARIO. This meeting will come to order.

Our witness this morning is Dr. Thomas F. Bates, who is science adviser to the Department of the Interior.

Dr. Bates, we want to welcome you here and thank you for coming back again. You were at the meeting when we had to adjourn at 11 o'clock. We have the same situation today, but since you are the only witness, we are in good shape for this morning's hearing. We are anxious to hear what you have to say.

STATEMENT OF DR. THOMAS F. BATES, ASSISTANT AND SCIENCE ADVISER TO THE SECRETARY OF THE INTERIOR; ACCOMPANIED BY HOWARD H. ECKLES, ASSISTANT TO THE SCIENCE ADVISER; JULIAN W. FEISS, STAFF GEOLOGIST, ASSISTANT SECRETARY FOR MINERAL RESOURCES; AND ARTHUR B. JEBENS, DIRECTOR, DIVISION OF MANAGEMENT RESEARCH, DEPARTMENT OF THE INTERIOR

Dr. BATES. Thank you very much, Mr. Chairman.

Mr. Chairman and members of the subcommittee, it was on June 1 of this year that I became the science adviser to Secretary Udall in the Department of the Interior. Prior to this, for the past 23 years, I have been a professor of mineralogy at the Pennsylvania State University. I believe you heard my honored chief speak before you yesterday, President Walker.

My most recent positions there were director of the Institute for Science and Engineering, assistant to the dean of the Graduate School, and assistant to the vice president for research.

You will see from my background that at this point in time I can speak from personal experience more adequately about relationships between NSF and the universities than between NSF and Interior.

However, in preparation for this hearing we have tried to make a thorough study within the Department as to the relationships which I wish to speak about this morning and the problems related thereto,

and I sincerely believe that the statement accurately represents the attitudes of the best scientists and research administrators in the Department. I personally am very pleased to have the opportunity to present it to you, and I would like to introduce to the members of the committee, Mr. Eckles on my left, who is the assistant to the science adviser, Mr. Julian Feiss to my immediate right, who is a staff geologist in the U.S. Geological Survey and attached to the Assistant Secretary for Mineral Resources, and Mr. Arthur Jebens, who is the Director of the Division of Management Research.

Mr. Daddario. The committee is happy to have all you gentlemen here.

Dr. Bates. I am sure that if there are detailed questions regarding the Department you will find these gentlemen more expert than I because of longer experience there.

In order to provide the committee with appropriate background information, I would like to preface my remarks on the Department-NSF relationships with a brief statement as to the Department's present and future role in the research activities of the Nation.

I think this will serve as important backup material for an appreciation of some of the points with regard to NSF-Interior relationships.

As you know, the Interior Department has many units within it, each charged with specific and somewhat different responsibilities. In a general way, however, the role of the Department as a whole can best be described as that of a technical consultant and trustee with respect to much of the natural wealth of the Nation: its minerals and metals (including the all important uranium and thorium); its coal, oil, and gas; the waters of its lakes, rivers, streams, and off its coasts; the fish that live therein; and the wildlife population that inhabits the land. Obviously, if the Department is to be the right kind of consultant and trustee, it must act on a fully informed basis of scientific and technical knowledge and in relationship to long-term, national interests. In those cases where the resources are renewable, as in water, fish and wildlife, the responsibility must involve every possible action that can be taken to maintain or even expand the supplies to meet new requirements. On the other hand, the expendable wealth—minerals, metals, and fossil fuels—must be recovered, beneficiated, and utilized with maximum efficiency and at minimum cost, taking full advantage of technical developments, alternative sources, or development of substitutes.

Finally, since the full extent of our potential natural resource estate is not known, and indeed changes in value as a result of advancing technology, the Department has to be engaged in a continuous process of exploration and evaluation and be aware of new developments in all related fields.

Figure 1 illustrates that, relative to Federal R. & D. expenditures in other areas of national concern, the natural resources program takes a back seat as far as Government funds for research and development are concerned. Although basic and applied research in industry on minerals, metals, petroleum and other natural resources adds approxi-

RELATIVE FEDERAL SUPPORT OF RESEARCH AND DEVELOPMENT BY SELECTED FUNCTIONS

FISCAL YEAR 1964

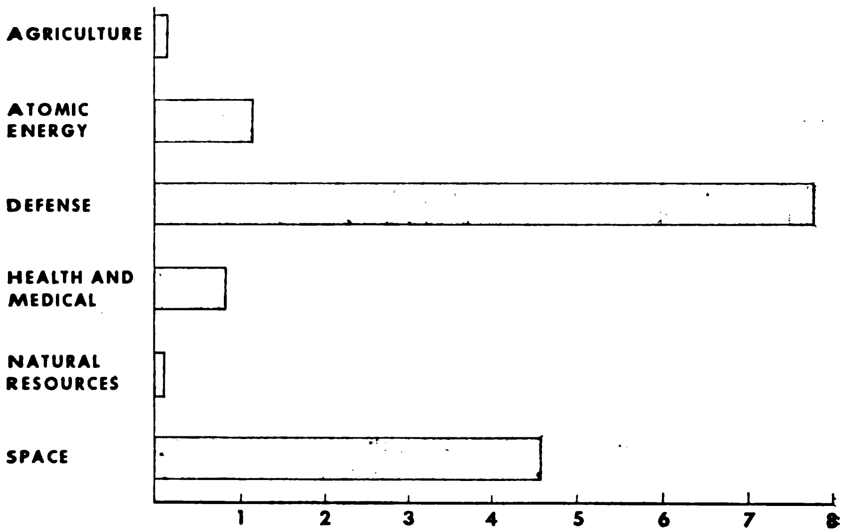

FIGURE 1

mately another $0.6 billion most of this is for short rather than long-range research. One can't help but wonder if we are sufficiently concerned about our basic wealth and our source of income and how to guarantee and, if possible, increase it for future generations, as compared with how we spend this income.

As the Federal agency having the greatest responsibility for the discovery, recovery, and—where possible—renewal of our natural resources, the Department of the Interior cannot properly discharge its obligations without being immersed in research activities of all kinds: applied and basic, in-house and extramural, laboratory and field, modest and expensive. Part of its responsibility is to develop ever closer and more effective relationships with all individuals and groups that can help it to carry out its many missions: universities, industries, other mission agencies and certainly the National Science Foundation.

The present research program of the Department, as might be expected, varies considerably in character and amount of funding from bureau to bureau. This variability is illustrated in figure 2 which shows the total research expenditure of each bureau and the in-house versus extramural proportions. It will be noted that three of the four bureaus with the largest research budgets spend the money largely in-house, whereas the three most recent additions to the Department; namely, the Office of Water Resources Research, the Office of Coal Research, and the Office of Saline Water, rely heavily on extramural research and development groups in helping to accomplish their missions. The amount of extramural funding that goes to universities is shown with other data in table 1.

DEPARTMENT OF THE INTERIOR
OBLIGATIONS FOR RESEARCH AND DEVELOPMENT BY IN-HOUSE AND EXTRAMURAL PERFORMERS
FISCAL YEAR 1965

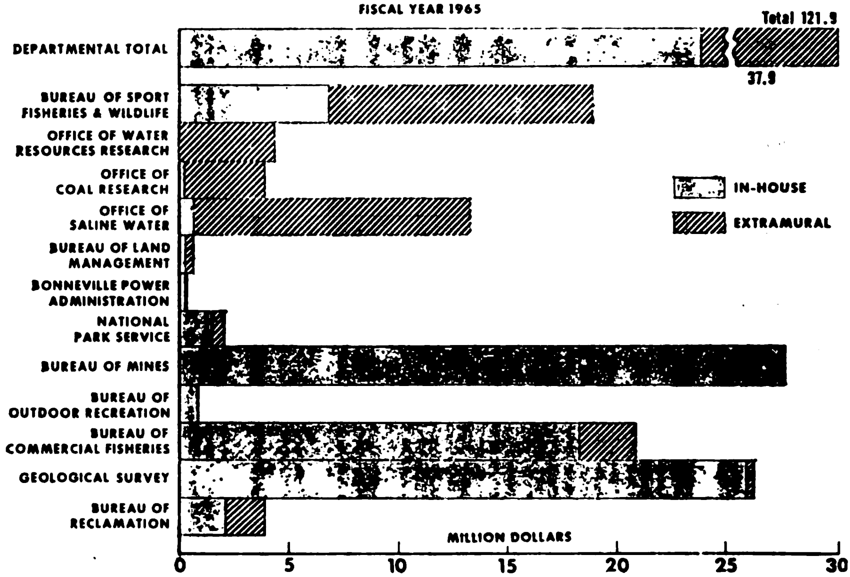

FIGURE 2

DEPARTMENT OF THE INTERIOR

TABLE 1.—*Obligations for research and development by performers, fiscal year 1965*

[Thousands of dollars]

Sport Fisheries and Wildlife	6,939	400	33	8	11,443
Departmental total	84,039	10,943	1,521	13,110	12,343

It would not be appropriate at this time to go into detail as to the Department's present research program and specific plans for the years ahead. With the chairman's permission, however, I would like to enter into the record at this point a copy of a letter from Secretary Udall sent in answer to a request from Mr. Daddario last fall to provide a brief description of program areas scheduled to receive major emphasis in the Department. This discussion included statements on numerous activities grouped under the headings of: Water resources, energy resources, minerals and geology, land resources, fish and wildlife resources, ocean resources, and ocean engineering. As this letter pointed out, the ability of the Department to implement properly the desired programs will depend in part on the successful resolution of

certain key issues some of which, such as relationships with universities, are very pertinent to these hearings and will be mentioned later.

(The letter referred to follows:)

DEPARTMENT OF THE INTERIOR,
OFFICE OF THE SECRETARY,
Washington, D.C., November 12, 1964.

DEAR MR. DADDARIO: In further response to your letter of July 29, 1964, we are sending you a brief description of projects which will receive major emphasis in our scientific research and development program during the years ahead. This research includes many significant programs now underway in the Department to improve the national capability for development and conservation of natural resources. Through rescheduling of efforts and addition of new programs at the request of Congress, there will be increased research on water resources, ocean resources, and environmental pollution as it pertains to welfare of fish and wildlife.

We have organized our information on research under categories of water, energy, minerals and geology, land, fish and wildlife and ocean resources and engineering. As we view development of this program, key issues become apparent and these are described in the final paragraphs of this letter. These issues will need to be resolved if the research program outlined is to have its maximum effect on the Nation's resource development.

WATER RESOURCES

Investigations in significant areas will be continued to elucidate hydrologic systems, provide basinwide water resources appraisals, provide information on ground water resources and other data for use in all types of water management.

There will be research on hydrologic principles and observational techniques. This includes studies of the hydraulics of water, movement, storage and flow in channels, lakes, glaciers, and in the ground, chemical reactions of water with aquifer materials, processes of evaporation and transpiration, processes of sediment transport in rivers, and hydrologic effects of man's activities.

Nationwide water data networks will be strengthened to obtain facts about the stage, flow, chemical properties, sediment content, and temperature of surface waters, and to monitor natural and manmade changes in ground water conditions. This includes depth to the water table and chemical quality of ground water.

There will be a program of research and training of scientists through the Water Resources Research Act of 1964. Water resources research institutes or their equivalents will be established in the States and Puerto Rico. Matching grants for research will be made to these institutes over and above a basic allotment provided by the act. Grants or contracts will be made to other research organizations and water resource agencies, including educational institutions that do not have established institutes. This program will be responsive to State, regional, and local water resource needs and to the use of multidisciplinary talents for meeting those needs.

Saline water conversion will be elevated to a new level of effort. We will substantially increase research to develop entirely new desalting techniques, to improve distillation processes and to develop the promising reverse osmosis process.

Development of large multistage flash evaporators for saline water conversion will be accelerated by a program of conceptual design studies to encourage new approaches and by building and testing modules to encourage new approaches and by building and testing modules and components. It is anticipated that research and design advances will justify construction in the late sixties of at least one dual-purpose plant in the range of 50 million gallons per day, using the multistage flash distillation process.

Weather modification is to be studied with the aim of increasing water supplies over water storage projects used for agricultural purposes and power generation. This will involve study of cloud seeding, particularly during winter storms rising over the Rockies. The objective is to increase snow pack and eventual runoff into storage reservoirs. This is to be a cooperative effort with other governmental agencies and universities having an interest and competence in weather modification research.

ENERGY RESOURCES

The fossil fuels, coal, petroleum, and natural gas which will supply the bulk of the Nation's energy supplies will be the subject of major research efforts. In addition to research to improve known detection and extraction methods, projects will be undertaken to develop new uses and techniques or to overcome particular problems hindering wider use of coal and petroleum. Among these will be efforts to convert coal to gaseous fuels, produce gasoline from coal, and develop a coal-fired gas turbine suitable for generating electricity in central-station coal-burning powerplants.

During the next several years research will be intensified on developing new means of producing petroleum and natural gas from low-permeability problem reservoirs by use of chemical and nuclear explosives and by use of unconventional supplemental energy sources.

Methods will be developed for determining causes of air pollution by automotive engines and of preventing such pollution. Problems of the stability of petroleum fuels in storage and in use under adverse conditions will be studied. Information will be obtained on the composition and utilization of heavy fractions of petroleum, particularly asphalt. Thermodynamic properties of numerous sulfur, nitrogen, and hydrocarbon compounds will be determined to provide basic data needed for air pollution and other research.

There will be fundamental and engineering research on oil shales. This will include determining the occurrence and properties of oil shales, the physical and chemical make-up of various shale oils and factors involved in converting the solid kerogen; i.e., oil shale, to oil. This will include experiments in in-situ extraction, a potentially improved method which eliminates mining of the shale before extraction of the oil.

Investigations are to be made into numerous opportunities in the energy field including those which use fossil fuels where increasing efficiency or supplying energy by new methods might lead to more abundant overall energy supplies. Particularly, there are opportunities to supply energy where the demands are unique. Included are the use of solar energy, development of fuel cells, further research and development in application of magneto hydrodynamics. Research and development is to be continued on extra high voltage transmission of alternating current and the use of direct current transmission for electrical energy transport over long distances.

MINERALS AND GEOLOGY

Research will be conducted to improve the Nation's mineral resource base. Basic geologic data and interpretations will be provided through reports and maps of adequate detail for appraisal of resources and determination of resource policy. This will also assist private enterprise in its search for mineral raw materials and its use of land such as for highway construction and urban and engineering developments.

Other research will be on geologic, geophysical, and geochemical principles and processes. This will provide new knowledge for exploration of hidden mineral resources, prediction of earthquakes and volcanic eruptions, and application of geology to space exploration, engineering problems, underground nuclear explosions, communications, and oceanography. Several of the research activities are expected to be reinforced and amplified by efforts of other scientific organizations in this country and abroad being coordinated under the international upper mantle program.

Mining engineering research will cover a wide scope and will be directed to translation of research results to engineering principles applicable to mining. An important phase is adaptation of mathematical tools, techniques of statistical analysis and operations research to mining problems in sampling, quality control, and systems analysis. An important segment of this area of research is large-scale field investigations under operating mine conditions to test the validity of developed theory and establish the parameters essential for engineering application.

Problems of waste material utilization especially iron and steel scrap are becoming more formidable as the accumulation of scrap automobile bodies mushrooms in junkyards throughout the land. Metallurgy research is underway to provide an economic solution to this vexing problem.

LAND RESOURCES

Research and investigations will be carried out to support management operations on public lands administered by the Department. Included with this will be related programs for the national parks and research to meet outdoor recreation planning requirements.

Research for public land management will concern a variety of disciplines and will be on soil and watershed problems, range, wildlife, forestry management, and resource use and protection.

A major effort in the national park system over the next several years will be research in environmental biology and ecology to preserve and manage natural areas of the parks. Practical problems in the maintenance of natural areas are resulting from access roads, visitor traffic throughout natural areas, fauna and flora changes in response to man's activities and natural evolution. Research is needed to gain information with which to interpret the results of the interaction of these forces and to form a basis for the design of future actions for park management and preservation. This research program which is relatively small at the present time should grow to be one of the principal research efforts within the Department over the next several years.

In the field of outdoor recreation, research is needed on a variety of subjects which will form the basis for the overall design and coordination and communication about national outdoor recreation systems. Included as subjects for research are the expected supply of recreational resources and facilities, current and future predicted demands, the effects of recreation on people and on society, the economic impact and results of allocations of lands and water areas among competing uses, and the Federal, State, and private roles in providing outdoor recreational opportunities.

FISH AND WILDLIFE RESOURCES

Major emphasis in research on fish and wildlife resources will be on pollution and its effects on the welfare of fish and wildlife. Problems of environmental alteration and pollution are becoming more acute as urbanization and industrialization progress. Many streams, lakes, estuaries, and inshore coastal areas which are all important to the production of aquatic species are polluted to some degree with wastes and pesticidal chemicals. It is known that pesticides and many types of industrial wastes can kill fish and shellfish in minute quantities. Present indications point to a continued increase in pollution problems and the need for major efforts toward an understanding of pollution and devising means for its abatement is needed. Expansion of effort in this field is planned.

Biological research is planned to ascertain the underlying reasons for decline in the abundance of certain fish and wildlife populations and to develop knowledge for forecasting future fluctuations. Studies are to be conducted also on the impact of natural and manmade changes in the aquatic environment. This research will include measurements of the abundance and survival rates of young forms, the effects of harvesting intensity and considerations on the type of harvesting methods used as they relate to attaining the most desirable production of commercial and recreational species.

A new opportunity in the field of food fish production is the possibility of aquaculture applied in large outdoor impoundments or in natural situations. Accomplishment of artificial production will involve further studies of both fresh water and marine species to gain an understanding of genetics and physiological and biological requirements. There will also be needed prototype facilities for water control and creation of facilities in enclosed bays, channels, and streams. The artificial culture of fish is one means whereby production levels can be maintained and possibly increased in the face of a changing environment through engineering and pollution.

OCEAN RESOURCES AND OCEAN ENGINEERING

The Department's program in oceanography and ocean engineering is scheduled for continuation as planned through the Interagency Committee on Oceanography. This will involve studies of the ocean environment to support an increased harvest of marine food and game fishes. Research on other types of marine resources will concern marine geology, hydrology, and the development of a marine minerals technology.

There will be a substantial program of support to States which results from the Commercial Fisheries Research and Development Act of 1964. Under this act Federal funds will be made available to supplement State funds on an approximately 75 percent Federal, 25 percent State formula. Research and development is to be carried out by States which will aid all aspects of commercial fisheries.

Increased attention is to be given to application of oceanographic knowledge to ocean resources development. This will include geological information as a basis for construction of coastal installations, the development and use of specialized underwater craft for marine mineral and fishery explorations and the development of new techniques for fish detection, harvest, and processing.

KEY ISSUES

Inherent to the development of the preceding programs are a number of general problems. The manner in which these problems are met will have a significant bearing upon the future course of the individual research programs.

(a) *University and industry relationships.*—The research programs of Government do not stand alone. It is important that the best talent be applied to any of the research problems that are encountered, and often the needed research competencies are in university or industrial organizations. This Department has been oriented to in-house research and development work with a minimum of contracts, grants, or other arrangements with extramural groups. Mechanisms must be found to reorient the research program to greater extramural effort. This will involve consideration of grant programs to universities, contracting authority for bureaus of the Department, campuses, the education of needed resources specialists, and many similar problems.

(b) *Information centers.*—It is important that there be some centralization of information about resource fields so that the Nation can be assured of total overall research plans which will be responsive to the Nation's needs. To bring such plans into being, to evaluate and coordinate research progress, and to apply the results of research to the national needs, it is necessary that information flow exist. Information centers will need to be established. It is not clear how many such centers are needed or how they should be organized. It is clear, however, that the need is pressing in all resource areas. The Department, with its basic obligations for research and resource development in such fields as geology, minerals, aquatic life, energy, and outdoor recreation and with its program scope related to regional and State problems as well as to national problems must find means for establishing information centers that will fill these needs.

(c) *Research in resource analysis.*—A need for information centers is paralleled by a need for analytical groups concerned with resources. Such research groups would study the methods of resource analysis, apply latest technological techniques to analyzing resource needs, and evolve national plans. Resource analytical groups should be part of river basin planning, regional water programs, energy utilization, regional interties, environmental pollution, and similar activities. They need to combine the best research talents from economics, sociology, and environmental behavior, as well as from the biological, physical, and engineering sciences. Some resource analysis research can be done within the individual resource areas, but there are broad principles which apply to any type of resource analysis. These would receive the attention of a broad departmental group.

(d) *Ecological survey and research.*—It is more and more evident that resources are tied together from an ecological point of view. What is done in one area of resource development will have an impact on another. Furthermore, our basic ecological system is not well understood. We must gain a complete base of understanding about our ecology before it is further altered or destroyed. Within the ecological system, there are many gaps that have never been examined thoroughly, such as the community of plant life or the community of animal life. Neither of these have ever been adequately surveyed. Just as we have the Geological Survey to carry on basic measurements and analysis of the earth's mantle, so we should extend this same principle to the things that live on and in the earth—its plants, its animals, and the manner in which they are interrelated. In short, we must know our environment and its ecological relationships before we can consider alternatives for changing our environment and altering man's place in it.

(*e*) *Ocean operational capability.*—Research that will enable us to exploit the ocean for food, minerals, energy, recreation, and fresh water, as well as research directed toward a basic understanding of the geological processes allied with the ocean, require an ability to move around in, to make measurements on, and to do all sorts of operations within the ocean. A chief limitation to the development of ocean resources research and to applications that will advance our use of the ocean rests in our inattention to this operational capability. It is important that the Department acquire an operational ability for ocean work. Research appropriations that might go to active research often go to the increased costs of running or supplying ships or to the development of underwater craft. With its many mission fields concerned with the ocean, it is quite important that the Interior Department be able to coordinate this activity at the level of an operating capability. The form which this takes is yet to be determined. It will probably involve the sharing of shore bases by a number of research bureaus and a common use of oceangoing facilities. It should provide a common operating capability for use of all researchers who have a mission in the environment.

Sincerely yours,

STEWART L. UDALL,
Secretary of the Interior.

Dr. BATES. Now, if I may speak specifically to the matter of NSF-Interior relationships, I would first like to point out that the degree of association varies considerably from one part to another of the Department. At one extreme are groups like the Bureau of Land Management and the Bureau of Outdoor Recreation which have very little contact with the Foundation. At the other are, for example, the Bureau of Commercial Fisheries and the U.S. Geological Survey which have a great many ties ranging from personnel participation on reviewing and advisory panels, the use of NSF-funded facilities, and many others. As another example, the Office of Saline Water has a formal arrangement with the Foundation providing for liaison regarding proposals of mutual interest, where these proposals are sent back and forth and reviewed by both groups.

A quantitative indication of the common concern of the two groups in certain general subject matter is given in figure 3. Strength in the biological sciences is focused in the Department in the Bureau of Sport Fisheries and Wildlife and in the Bureau of Commercial Fisheries.

The situation in the behavioral and social sciences should be mentioned primarily because of the rapidly emerging importance of such areas as animal behavior in the areas of fisheries and wildlife, and of human resources studies in connection with land management, outdoor recreation, and the future of our national parks. General similarity of concern and responsibility in the physical and engineering sciences is evident from the figure and exists, of course, because of the nature of the missions of the U.S. Geological Survey, Bureau of Mines, the Office of Saline Water, the Bureau of Reclamation, and other groups. It is within the scope of the life, physical, and engineering sciences that Interior and the NSF could benefit from an expanded program of consultation and interaction in shaping the cooperative research and training programs.

In our opinion NSF-Interior relationships are characterized by the following areas of effectiveness:

1. The use by NSF of Interior scientists for proposal evaluation and, in a few cases, as members of advisory panels. The Department has also turned to NSF personnel for similar assistance.

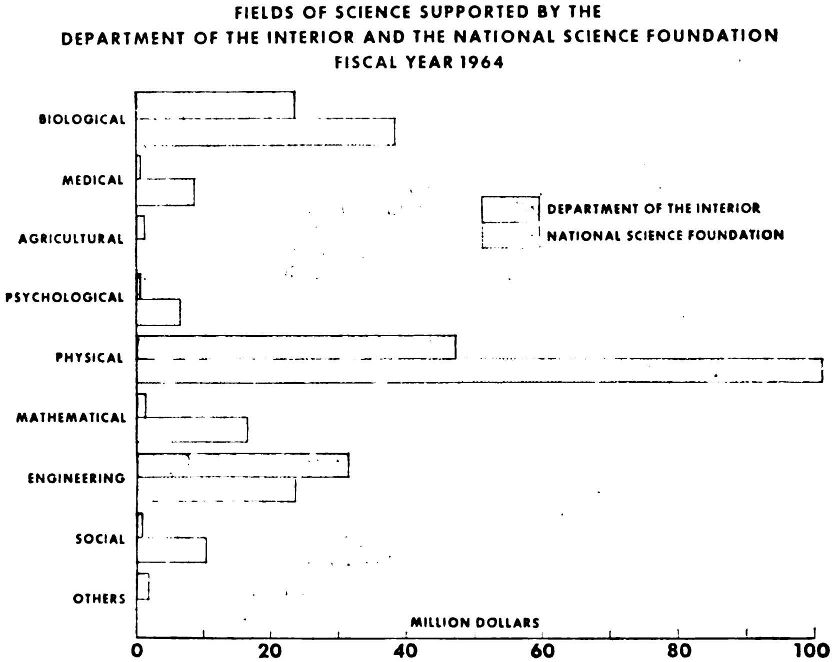

FIGURE 3

2. The availability of NSF-provided special facilities such as oceanographic vessels.

3. The availability of data collected and collated by the NSF on the many aspects of the state of science and scientific manpower in the United States.

4. Interaction through coordinating committees; for example, the Interagency Geophysical Discussion Group, the Interagency Committee on Oceanography, and so on.

5. Participation in NSF-supported programs such as the U.S. Antarctic research program and the United States-Japanese cooperative science program.

6. Some attendance of Interior scientists at NSF-sponsored summer institutes and in a few cases where NSF fellows, both postdoctoral and predoctoral, have done their research in Department laboratories.

In the areas where these relationships exist, they are cordial, close, and advantageous to the Department. One major need is for more of them.

In the opinion of Interior research administrators, areas presenting problems are (1) communications; (2) lack of sufficient research support in areas of major concern to the Department; (3) a tendency of the fellowship and trainee programs to attract the best students away from the areas and problems challenging the Department; and (4) lack of a management policy that attempts to assure adequate coverage of all science areas from the standpoint of the research and manpower that is needed.

The problem of communication is listed first because improvement in this area is essential to the solution of all problems in our opinion.

By communication is meant the development of a working partnership; not simply getting together for lunch. The present situation, as viewed from Interior eyes, is somewhat as that pictured in the oversimplified diagram below where the Foundation, Interior, and the universities are at the corners of a triangle enclosing the basic research goals of common interest to all three. The excellence of the working relationship between the NSF and the universities is symbolized by the solid line connecting them. Communications between the Department and universities is spotty—very good in places, poor elsewhere—and efforts are being made to move from a dashed to a solid line relationship here. The areas of effective NSF-Interior interaction mentioned earlier are only sufficient in number and size to justify a dotted line.

The situation might be compared, by a simple analogy, to that of three hunters with nets trying to close in on a wild animal, which in our case represents the research objectives. If we are going to capture the animal, this means perfectly coordinated teamwork and no holes in these nets. We need betters coordination and a tighter net between Interior and both its other partners, particularly NSF.

Mr. DADDARIO. Dr. Bates, you refer to better communications and say a working partnership ought to develop. Do you mean that before informal relations between one agency and another can develop in a fruitful way, that there must first be a formal setup which establishes a relationship from which informal relationships can then be helpful? In this instance you do have some informal activity, but not enough formal communications between the two agencies.

Dr. BATES. I think it is natural in the way of things that the informal relationships tend to develop first and lead to more formal ones. I think we have a great many informal relationships between these two organizations. Possibly, however, we need still better informal relationships at high levels in order to subsequently have more formal relationships at high levels.

Mr. DADDARIO. Many other witnesses have indicated that they have good formal relations, but that the informal activities are probably more important. In your case, there seems to be no base upon which to work.

Dr. BATES. I think it is the other way around in our operation. I don't think there are nearly enough formal relationships that have as yet been established, and probably not nearly enough informal ones either. I believe we need working committees with assignments to look at the areas of research that are of common and mutual concern to the Science Foundation and the Department of the Interior. These committees would first presumably evaluate where the gaps are in these research areas and presumably should have ideas as to how they might better be covered by Federal funding and also by better relationships between the two groups.

Mr. DADDARIO. If there is this desire for such interaction, what has prevented it?

Dr. BATES. I think it is simply the fact that both groups, in the usual situation where they are bound by limited amounts of funds, have very specific missions that require that they move in certain directions—relative to universities in the case of NSF, relative to certain specific missions in the case of Department units such as the

Bureau of Mines and the U.S. Geological Survey. The funding has not been sufficient to cover the total area of the research spectrum from fundamental research as represented by NSF and applied research as represented by the Department of the Interior. We have at present two peaks, one at the Interior end and one at the NSF end of the question. Both of these peaks need to be broadened at the base into pyramids which join on a common base even though the peaks of specific interest and responsibility are separated. I noticed, Mr. Chairman, that you pointed out during Mr. Ripley's testimony that other witnesses have made this same point with regard to the need for NSF to move closer to the other agencies and vice versa. I am in agreement.

Mr. DADDARIO. When funding is scarce, NSF has moved closer to the other agencies, and they seem to get along better. You are in that situation without having had the opportunity for larger funds previously. There should be a closer relationship so that the funds could be better utilized. You have indicated a problem because some of the fellowships and grants attract people away from subjects in which you are interested. Since this is the case, there would seem to me to be a special need for a closer relationship so that this could be worked out.

Dr. BATES. I agree. I think that is the main point I am trying to make that we should have people who are formally charged with discussing the grant programs of the National Science Foundation——

Mr. DADDARIO. It is not the lack of funds which keeps you apart actually although there seems to be an indication that this is the reason why you are apart. The move has not come, and it ought to.

Dr. BATES. I agree, it certainly could have come even though there haven't been any more funds than have existed in the past. Let me say here, however, that I don't want in any way to make derogatory implications about the past role of the National Science Foundation. I think this is a two-way street in which there is a need for a great deal more work on the part of both groups involved. I don't think the past relationships have been at all unpleasant or illogical, but I think we can move into the future by bringing these two important units of our Government closer together.

Mr. DADDARIO. Was the reason there has not been better coordination because of the fact that sufficient effort has not been made in that regard or because your major activities normally have been in a different area?

Dr. BATES. I think both these factors are very important. I must admit that the situation is of great personal interest to me. In much of my scientific as well as administrative work in the university I have been in close touch with various NSF programs and, as a consequence, I feel pretty well informed on NSF-university relationships. In the month and a half I have been in the Department of Interior I have been impressed with the close relations between individuals in the Geological Survey, for example, and the Earth Sciences Section of the Foundation. I am also impressed, however, with the lack of knowledge in many units of the Department of Interior as to exactly what the NSF is trying to do, what its programs are, and what its aims are relative to Interior's objectives. There appears to be a lack of communication that exists I think, because of the natural tendency for each Federal agency to take care of its own operation. I should add at this point that I have been very impressed with the activities of the

Federal Council in working on exactly this problem of bringing the agencies closer together.

Mr. DADDARIO. Can you see at the present time a good opportunity to do this?

Dr. BATES. Tremendous opportunity, one reason being that the Department of the Interior is trying to move more strongly into areas such as improved Interior-university relationships, which will automatically bring them closer to the NSF also.

To continue with my statement, problem areas (2) and (4); namely, lack of research support in some areas and lack of management policy to assure complete coverage in science, both exist because of NSF's reticence—up to now, perhaps, a proper one—to assume sufficient leadership in or to even press for science management within specific areas of science. NSF coverage of research in any given field is determined by the nature of the proposals that are submitted and approved. For better or worse no organized or directed attempt is made to assure representative coverage or to orient the research participation. The university researchers who submit proposals acceptable to panels, those panels being composed largely of other university scientists, determine how well that field of science will be covered, during the period involved, by NSF-supported basic research. Gaps or imbalances in the coverage may or may not be noted, and even if recognized, do not stand much chance to be corrected while this system operates. Such a policy makes it difficult to relate NSF-supported research to agency programs and objectives, particularly when communications between the three parties is, in our opinion, inadequate.

In the scientific manpower area there is real concern among Interior's top research administrators that NSF and other fellowship programs influence students in the direction of basic rather than applied research, thereby making it increasingly difficult for mission-oriented agencies to obtain top talent. In this regard, the emphasis on trainee programs is welcomed as an indication that some degree of management is being applied to assure a more equitable distribution of funds among subject matter areas.

With the full realization that the problems cited above are difficult and of a long-range nature, the following areas of improvement are indicated:

1. Improve communications by establishing NSF-Interior coordination and planning groups charged with the recognition and solution of problems affecting the progress of science in areas of mutual concern.
2. Set up NSF-Interior-university committees in appropriate subject matter areas charged with the responsibility of reviewing research coverage in the given fields, discovering gaps and imbalances and recommending ways of closing them.
3. Make much more use of Interior scientists on NSF review and advisory panels.
4. Establish cooperative programs involving the use of Interior laboratories and equipment for the training of NSF-supported undergraduate and graduate students.
5. Increase the proportion of traineeships allocated to the departments and interdisciplinary graduate programs operating in the areas of the "environmental" and applied sciences (for example, mining

engineering, metallurgy, ceramic technology mineral beneficiation, fuel technology, chemical engineering, materials science, regional planning, and conservation).

In conclusion, Mr. Chairman, I should like to make it clear to you and the committee that we in the Department of Interior fully realize that our relation with the National Science Foundation involves a two-way operation in which the Department has a responsibility as well as the National Science Foundation. We are working hard to increase our relationships with universities and can logically look to NSF for assistance in this area. We hope that the Foundation will be in a position to assume leadership in the new directions that we feel science must take in the next 15 years by bringing mission-oriented agencies like Interior together with the universities and the NSF into a comprehensive program of science with fewer gaps and closer communications.

Again, may I thank you for this opportunity to appear before you. I will be glad to respond to any questions that you or other members of the subcommittee may have.

Mr. DADDARIO. Dr. Bates, could you go into a little detail as to the relationship that now exists between Interior and NSF? How does that work? What are the means of communication? What areas can you point to?

Dr. BATES. I think the first thing that impresses me is the number of coordinating activities where members from both groups serve on the various panels that are set up by organizations such as the Office of Science and Technology. There are also an increasing number of areas of mutual concern as, for example, that of United States-Japanese relationships. We have just concluded a second meeting of the United States-Japan Panel on Natural Resources, at which both NSF and Interior were well represented. As another specific example, Interior and NSF representatives serve on the Federal Council for Science and Technology and its various subcommittees such as the Interdepartmental Committee for Atmospheric Sciences. We are working very closely with NSF and other agencies in this area.

The second example of close relationships is that a number of Interior scientists are used to some degree, in the same way as university people, in the review of NSF proposals. There is no inclination, as far as I know, on the part of the Science Foundation to exclude as panel members people from the U.S. Geological Survey, Bureau of Commercial Fisheries, and other Interior bureaus simply because they are in the Government. I feel that there could be more use of our scientists, however.

From the standpoint of the use of the Science Information Exchange and the tremendous amount of data provided by the NSF, such as that that we have tried to use quite extensively in preparing for these hearings, the NSF has done a fine job of providing all mission-oriented agencies with useful backup information on science and matters related thereto.

The U.S. antarctic program provides a very good example. Here is a program for which the National Science Foundation is responsible but where the Geological Survey receives appreciable funding to conduct a large amount of mapping and research. In another case—the Indian Ocean program—NSF oceanographic vessels were used

extensively by Bureau of Commercial Fisheries scientists. The NSF National Center for Atmospheric Research in Boulder has very close ties with people in our Department that are working on meteorological problems. Thus, in many areas such as these we can point to very good relationships between the NSF and the Department of the Interior. There is opportunity for a good deal more interaction, however.

As an example of one type of Interior activity that might involve the cooperation of the NSF or some other foundation, I might cite a program now being planned by the U.S. Geological Survey and the National Association of Geology Teachers where it is hoped that a foundation may be willing to provide support for a certain number of students to attend geology field camps during the first year of their graduate work. The U.S. Geological Survey—on the basis of the results of the students' first year work—would put a certain number of them on WAE (while actually employed) status on their field parties during the following summer in order to move them one step farther toward actual, practical geological mapping.

Similarly we have many Bureau of Mines laboratories scattered throughout the country, many in cities with good universities. We feel these laboratories might relate more closely to departments of mineral beneficiation, metallurgy, chemical engineering, and others in these universities. If we could get an NSF-Interior operation going, where students with NSF support might use the facilities and laboratories of the Bureau of Mines, this would do several things. It would provide both financial and facility support for the student. It would strengthen Interior-university-NSF communication. It would give the students experience in a Government laboratory and a feel of what the needs are in their chosen area of work.

Mr. DADDARIO. Career opportunities and things of that kind?

Dr. BATES. That is correct.

Mr. DADDARIO. Would you go into greater depth on the point you have raised about NSF not assuming sufficient responsibility in science management within specific areas of science?

Dr. BATES. Let me say first of all I realize the word "management" is a rather touchy one to use in speaking of any scientific activity. However, I think we must realize that in deciding that a certain amount of money should go into the physical sciences, a different amount into the engineering sciences, and still other funds into the biological sciences, a management operation is already taking place relative to the balance between the broad areas. What I am suggesting here is that this operation might also be used at a sublevel so that within the engineering sciences, for example, the total funds available would be appropriately divided among the various fields of engineering science. From the standpoint of doing the best for this Nation with regard to total coverage of science, I believe the agencies responsible for providing the funds must make decisions on such questions as: Is civil engineering getting enough support relative to mining engineering, relative to industrial engineering, relative to metallurgy, and so on?

Mr. DADDARIO. You are referring then, to better ways of establishing national goals and objectives and of recognizing the technical levels

available to accomplish those ends, and to the basic choice we make to accomplish these end objectives?

Dr. BATES. Better ways to establish them and as I say to accomplish or meet them. I am impressed by reports like this,[1] which is one of seven reports put out on the general subject by the National Academy of Sciences. This one is on mineral resources, and contains the recommendations of a committee headed by Dean Frasché of the Union Carbide Ore Company. It would not be pertinent to quote all of their recommendations but among them are: that basic research on the chemistry and the physics of the earth's crust should be augmented during the next decade at a rate of 25 percent per annum; that the research program in mineral extraction should be expanded at the rate of 15 percent per annum during the next decade. There are seven or eight such recommendations based on a detailed study of our national needs in the mineral resources area. The point I want to make here is that to meet these needs we must go about it logically, not primarily on the basis of the subject matter distribution of proposals that the scientists just happen to be putting into the National Science Foundation, but in terms of careful fund distribution based on all applicable criteria. The planning involved obviously cannot and should not be the responsibility of the Science Foundation alone, but because of the role the Foundation is playing in American science, it must assume a large part of the responsibility.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Mr. Chairman, I would like to ask a definition or two. In the first place, what does the study of hydrology embrace?

Dr. BATES. I would say all aspects of the water budget, where the sources are, how water flows through the crust of the earth, how it is measured, where it goes, and so on.

Mr. DAVIS. In other words, you are not studying water itself so much as what it does and how it interacts with other things?

Dr. BATES. That is right.

You can't study anything thoroughly without relating it to its environment.

Mr. DAVIS. I have been wrestling with the difference between science and engineering for a good long while, and you use the term "engineering sciences." Just what does that mean?

Mr. DADDARIO. Did you throw that in there just to confuse Mr. Davis?

Dr. BATES. I think the reason for some of the confusion is because of the traditional development of these fields. At Penn State, for example, we have a college of engineering and across the campus, a college of science. There was no confusion as far as I could see 15 or 20 years ago in that there were distinct differences. Most engineers at that time were not getting Ph. D.'s. The scientists were not applying themselves primarily to the day-to-day problems of science at least in Ph. D. thesis-type research although many students subsequently were employed by companies concerned with applied research. The situation has changed tremendously in that it is recognized by engineers that they must now have a much more detailed knowledge of the physics and chemistry related to their chosen area of research

[1] Mineral Resources: NAS–NRC Publication 1000–C, 1962.

and development; whereas the scientists, who appreciate that their basic research may very soon find application, are well aware of the importance of knowing more of engineering. I realize I am not answering your question very directly, but I don't think there is a direct answer in that this is a continuous spectrum which can be talked of in terms of science and basic research at one end and engineering and applied research and development at the other. There is a gray area in the middle where the transition is made from fundamental to applied, and the term "engineering sciences" is used to cover part of this gray area. The increasing importance of interdisciplinary activities where science and engineering combine to work on problems of all types also encourages the use of the term "engineering sciences."

Mr. FEISS. Up until, you might say, a relatively few years ago, I would say about the time of World War II, we had a tendency to compartmentalize engineering from science. Science was considered primarily as the search for truth, the search for the laws of nature that govern various phenomena. That was the definition. Engineering, on the other hand, was the application of those laws to human benefit and human welfare. It became evident I think during the war particularly (you recall the history, for example, of the Manhattan project) that you had to coordinate to a very close degree the scientific findings along with their application. I think that essentially this is where the change in definitions comes about, where the merger takes place you might say.

In other words, it is recognized generally today that science does not exist in a vacuum purely as a search for truth, but that it should be pragmatic, it should have some application. I think that most engineers are beginning to appreciate the fact that, for example, the techniques of building a bridge or laying out a highway are not enough. You have to go beyond that. You have to figure what will be the effect upon the city of Washington, for example, if you are going to put in an arterial highway. Thus engineering itself has broadened. We wrestle with these problems on the Engineering and Scientific Manpower Commissions. The Scientific Manpower Commission is, of course, under NSF. I think it is an important point to distinguish that there is a tendency toward a merger in thinking.

Mr. MILLER. Will the gentleman yield?

Mr. DAVIS. Certainly.

Mr. MILLER. I, too, have wrestled with this problem, and I always find it applied to engineering, engineering scientists, and scientists. Are there any other disciplines of learning where this takes place? In the medical profession do you distinguish between the practitioners in medicine and the people who do research? Don't you have to accept more or less that any man who can do one can do the other, and if he is going to be good must do some of the other?

Dr. BATES. I think the existence of a social science area is in itself a recognition that we must bring science and humanities together in the broad scale.

Mr. MILLER. Do you think that the scientific community through the Academy of Sciences and the Academy of Engineering perhaps should undertake to make some redefinitions to bring these terms into modern connotations, because there is always this confusion I believe

that comes up when we get into this field? Shouldn't someone start to lay down some guidelines? We recognize the very gray areas that exist and will always exist. But couldn't we begin to perhaps lessen them so that we could have some guidelines in these fields?

Dr. BATES. I think in essence that is part of what I am suggesting here. I am not too worried about the definitions, as such. They are extremely useful and important. However, I believe in these areas things——

Mr. MILLER. If I may interrupt you, Doctor, they are very important. If the members of this committee can't reconcile these things, the Members of Congress who have not had the privilege of being exposed to people such as yourself would probably get quite confused. When you come to ask for money, we sometimes can't answer the questions.

Dr. BATES. Yes, I agree 100 percent with you. I think I would revise the way I started that statement to say that it is important o recognize that the definitions of today may not be the applicable definitions of tomorrow because of changes that take place. However, I would support your statement that we need, as of today, to have good definitions.

Mr. MILLER. I started life as a civil engineer and worked at it in the West before World War I, but civil engineering in those days was almost synonymous with surveying. I remember when the California Highway Commission was established in 1911. Up to that time, we built roads empirically. All of a sudden we began to find out that in certain types of soil they didn't hold up. When the department established a division to research this and to standardize materials, some people thought this was going far afield. If you wanted to build a road, you got a four-horse scraper, went out, and put a top on it. I don't know that we have exhausted all the research as to the highways. We are still learning a lot about it.

Dr. BATES. This is very pertinent and it bears on your point. I was quite interested in a column appearing this morning in the Washington Post; maybe you noticed it, on underground roads becoming a feasible answer to city needs. I brought it in because it provides an example that relates to one area of concern with which we are dealing here: the need for much more rapid tunneling to expedite all kinds of underground construction for subways, utilities, Department of Defense installations, and so on. This sounds pretty unrelated to the need for basic research until you appreciate (and this is where definition and distinctions between science and engineering come in) that you can't do the ultimate in terms of putting a tunnel through as fast as possible without knowing more than we do now of the science of rock mechanics. This involves detailed knowledge of such things as the composition and texture of the rock, how it withstands certain pressures at certain temperatures, and so on.

Mr. MILLER. The Comstock lode in Nevada was worked out because there was too much hot water in it, and they didn't have pumps. Then a man by the name of Sutro decided to run a tunnel under the mountain and drain the hot water off. He made a deal with the landowners to get 20 percent of the profits. It used to swell closed, and they would have to go into there and open it again. He did his job and he got a lot of money. It benefited San Francisco a great deal.

Dr. BATES. This relates to one of my points, basic research versus applied research, to get back to the question of Mr. Davis. The area of rock mechanics, involving detailed knowledge of strain and stress on rocks, is pertinent at one extreme to our knowledge of the continents, crustal movements, earthquake prediction, and volcanic action, and at the other extreme to such practical questions as to how well the roof of a coal mine is going to hold. Here we have an example of a situation where there is no doubt about the NSF assuming the responsibility in supporting research on the earth's crust, and there is no doubt about the Bureau of Mines assuming the responsibility of working on the problem of the room in the mine. In between, there are many gaps where neither group can now assume responsibility.

Mr. DAVIS. Then you have engineering scientists and scientific engineers, both.

Mr. FEISS. I think a very great difficulty here is the line between chemistry and chemical engineering today. With reference to the manpower commission work, it was interesting to observe that the chemical engineers were represented on the scientific manpower commission as well as on the engineering manpower commission largely because it was recognized that to be a chemical engineer you had to be a chemist first.

Mr. MILLER. Where do you draw the line between chemistry and biology?

Mr. DAVIS. I notice you set forth the R. & D. dollar figures for fiscal year 1964. Through our work on the NASA budget each year, I know this space figure. If you took the second word away, "development," you would have a small figure left. I forget what the exact figure is.

Dr. BATES. I can give it to you. I have them here.

Mr. DAVIS. Would you insert those in the record?

Dr. BATES. I will be glad to.

(The information referred to is as follows:)

Obligations for research and development for the functions shown in figure 1 of my statement are as follows in billions of dollars:

	Research		Development
	Total	Basic	
Agriculture	0.17	0.06	0.008
Atomic Energy	.33	.26	.86
Defense	1.20	.20	6.42
Health and medical	.84	.28	.003
Natural resources	.24	.13	.03
Space	2.78	.68	1.89

Source: "Federal Funds for Research and Development," vol. XII, 1962-64, pp. 128 and 129.

Mr. DAVIS. In the Interior Department, I recognize that the development of saline water conversion would require a good bit of money. Are there other areas where you spend much money on development or does most of your money go toward research?

How would Interior's budget divide as between research and development? I do not ask for the specific figure, but I just wonder if your research would be only a small fraction of the total.

Dr. BATES. No, it is the other way around. I will be glad to get those figures for you. I didn't bring them with me.

(The information referred to is as follows:)

In fiscal year 1965 our estimate of obligations for development in the Department's total research and development effort was $21.2 million. This is slightly over 17 percent of the total of about $128 million for research and development.

Mr. DAVIS. That is all I have, Mr. Chairman.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. I just wanted to explore a more or less philosophical point with you. I recognize the validity of the opinion that you are making about science management, the need to insure that we have an adequate coverage of all the fields. We have brought this point up once or twice before.

Today we are getting a primary emphasis on certain areas which became important as a result of their relationship to defense and the military. Obviously with the development of nuclear weapons during World War II we had a very great interest in basic physics, mathematics, and chemistry. The AEC is sort of a spin-off of a military development, and similarly NASA program is a spin-off. There is much concern with other aspects of basic science, but there is a great deal of overlap between physics and mathematics that concern AEC and the space program. So we have seen a great deal of emphasis on a relatively small part of the total science spectrum stemming from this relationship. What we are seeing today and what you are pointing out is the need to broaden our concepts. If we could show that the earth sciences and so forth had a direct relationship to national defense that was more important than nuclear weapons is, I am sure we would see a great infusion of money into the earth sciences. The goal of the NSF obviously was to make certain efforts to change this management picture, but the emphasis still is on these original areas of basic science. The goal of these hearings has been to investigate whether we are now ready to move on to a broader approach, and I think your contribution has been very valuable from that standpoint. You have described some areas which you title "Environmental" on page 15 which include mining engineering, metallurgy, and so forth. But this does not exhaust what might be described as environmental sciences?

Dr. BATES. By no means.

Mr. BROWN. You have listed those which are of particular concern to your department?

Dr. BATES. Yes, I did not mean that environmental and applied were the same here. The statement may be somewhat misleading. Seven of the ten subjects listed in parentheses there are largely related to the minerals sciences as distinct, although not separate from, enviromental sciences such as ecology. In this latter connection I was very interested in Dr. Ripley's statements before the committee last week with regard to preservation of cultures. As an illustration, I have a colleague who is now working on National Science Foundation sponsored research in the Everglades. He is a paleo-botanist who has been doing very fine research on the present and past effect of the salt versus fresh water environment on the cyprus, palmettos, saw grass, and other plant life of the area. It is partially through his work and the work of others in that area that we are beginning to understand the very

drastic effect that the canals are having on the Everglades. If this type of work had been done 10 years before we got into the situation where we needed these canals for the benefit of the human population, then appropriate plans could have been made to assure that engineering for human needs did not cause drastic damage to the natural environment.

In the same vein there are many places where the Bureau of Reclamation is building dams. We are making every effort to show proper concern for the environment: what is the effect of a given dam on the animal, the plant life of the region, and so on. However, we are not confident that we are doing nearly enough research with regard to natural animal and plant populations and the effect of man on the environment.

Mr. BROWN. You use the term regional planning and conservation here.

Dr. BATES. They are certainly part of environmental science.

Mr. BROWN. Really, even here you are talking about regional resource planning, using resource as a fairly broad term. You refer, for example, to the economic planning which would involve the location of businesses and the economic interaction of the community with other communities.

Dr. BATES. I am not referring specifically to that except to point out that when you talk about regional planning this is one of the best examples of interdisciplinary activity involving the physical sciences, the social sciences, and engineering; because if you are worrying about the economics of the region you must know what the mineral resources are in addition to how the population is going to use them.

Mr. BROWN. If Interior were to try to integrate all regional planning, you would probably find a lot of objections from the Commerce Department and various other agencies?

Dr. BATES. Oh, yes.

Mr. BROWN. Do you feel that the Department of the Interior has had, in a budgetary sense, all of the funds that it would usefully be able to use in this area?

Dr. BATES. There is only one answer to the question. "No."

Mr. BROWN. You haven't exhausted all the frontiers of knowledge then?

Dr. BATES. We are working hard at it but we haven't gotten there yet.

Mr. BROWN. I have a feeling that a part of the pressure on NSF to support some of these things comes sometimes from the fact that NSF has been more successful in getting funds for these things than the mission-oriented agencies feel this is a way they can get funds. I am not at all sure that perhaps the answer is not an expansion, assuming we can make a suitable differential of the research funds for the mission-oriented agencies together with a greater emphasis on this coordination and integration between agencies that you have indicated.

Dr. BATES. Yes.

Mr. DAVIS. I was going to point out that there is a factor maybe of glamour involved as well as a factor of competition with the Communist world which may enter into the fact that other agencies have been so abundantly blessed with funds. I have seen witnesses come before our full Committee on Science and Astronautics, where committee members

would ask, Could you use some more money in the space program, and the witness would answer, "No."

Mr. BROWN. I can give you some specific examples of this, if you will allow me. I made a specific inquiry to the AEC with regard to whether or not they could use additional funds for fusion research which is attempting to use hydrogen fusion as a source of power. I was told that they couldn't, that the money they were spending was all that they could use considering the state of the knowledge and the number of scientists trained in this particular field.

Dr. BATES. I would like to point out to the committee that points along the line that I am making will be coming to the attention of Congress with much greater frequency because we are moving from the era where we could skim the cream of our mineral resources into an era where, for a variety of reasons, we must do a great deal more research in order to get the same payoff relative to what is available in the ground. A specific reason (and there are a number that might be pointed out) is that as the developing countries grow in stature they will have the ability and the need to use the mineral resources that they are now exporting to the United States and other countries. The United States in 1962, according to this report,[1] was the major producer of only 8 of the 16 major metals or their ores. We are becoming increasingly dependent on foreign sources for many mineral commodities. Another pertinent fact is that in about 1900 we could only mine copper ore that had a very high grade of about 6 percent contained metal whereas now we must use grades of only 0.8 percent. This means continuing improvement in technology. I am sure you are all familiar with this. The point I want to make is that we are moving into an increasingly difficult period from the standpoint of getting the most out of the crust of the earth. This is essentially saying we must have more research, basic research.

Mr. BROWN. I think it is going to be increasingly important that in our competition with the Communist bloc we must get across the idea that competition in the pursuit of excellence must not be confined to a very narrow sphere, as it has primarily been in terms of the expenditure of basic research funds, but should be across the board. Otherwise, we are going to lose in some areas that may not seem very important to us now, but 15 years from now are going to be all important. If you can work out some tie-in in this type of competition, it might make it easier to get some budgetary allotments. I have no further questions, Mr. Chairman.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Dr. Bates. I would like to ask if it is fair to say, in the area of earth sciences and understanding our natural resources, that considerably more money is expended by the private sector of our economy relative to the Government effort than there might be in some other areas of the physical sciences.

Dr. BATES. That is correct.

Mr. CONABLE. Is there quite a bit of basic research conducted by industry, let's say the petroleum industry, for example, relative to such scientific fields as seismology, and if this doesn't have some effect of mitigating the need in this area relative, say, to the space area, where there is no immediate hope of profit or utility?

[1] NAS–NRC Publication 1000–C: Mineral Resources.

Dr. BATES. This is certainly a factor. This is the reason I pointed out with regard to this first figure that in the natural resource area the industries themselves are contributing an additional six-tenths of a billion on R. & D. The problem comes with regard to the basic versus the applied research. Certainly in the petroleum industry you can point to certain of the companies that are doing terrific jobs with regard to basic research, but the funds expended are small relative to the amount of many that the total petroleum industry is putting into the applied problem of getting oil out of the ground right now, rather than worrying about what we are going to get out 20 years from now.

Mr. CONABLE. The Interior Department must deal with lots of companies in the course of a year with respect to lumber or timber contracts, for instance. Do you impose any conditions on them with respect to research, or are the conditions limited entirely to simply the wise utilization of natural resources? How far do you go?

Dr. BATES. I will have to ask if one of these gentlemen can speak to that. I have not been with the Department long enough to give you the answer.

Mr. ECKLES. I could speak in a general way, but I do not have specific information on the subject. The situation very likely is that through the leasing allowance—for instance, through Bureau of Land Management on public lands—that they would be allowed to harvest the resources there without a requirement to do any specific task as far as research is concerned. They would be required, of course, to follow prescribed conservation practices.

Mr. MILLER. But the lumber resources come more under agriculture, don't they?

Mr. ECKLES. That is correct.

Mr. MILLER. Most of the big lumbering companies today—some of those who were the biggest violators in the past—have come to realize that they have to replace their timber. Timber is a crop, and some companies plant two trees for every one they take out.

Mr. CONABLE. I simply wondered whether the Government, the Interior Department specifically, tried to stimulate research quite beyond what you might have direct control of through your public policy with respect to exploitation of natural resources. I imagine it would be something that would be difficult to do.

Mr. ECKLES. This is rather diffuse. One of the ways this is done is to encourage industry to carry out research on their own, which has a direct bearing on the program that the Department is carrying out. It is a dialog or exchange of information between the technical staffs in the Department and their acquaintances within industry. The areas of mutual advantage are often explored, and this does bring industry along to do its own research.

Mr. DADDARIO. Mr. Chairman.

Mr. MILLER. On table 1, under the Office of Water Resources Research, I notice you spend no money in-house, but through universities you spend about $4 million a year. One of the men that helped to compile that book you were just quoting from minutes ago, I happened to sit next to him the other day, and we were talking about the future of the country in regard to water pollution. I talked about some of the problems that we were having in California, and that this stuff would be pumped eventually to the sea. He said: "You are going at it backward; why don't you reuse it?"

Is anything being done on the reclamation of sewage water for domestic and other use?

Dr. BATES. There is a great deal being done, both at the university level and as related to the Department of the Interior. The Department, through the Bureau of Reclamation, has had a contract with the University of Arizona for just this purpose for the past 2 years. Speaking from my own university experience we have a project doing just that in Pennsylvania. The effluent from the sewage plant contains detergents—nitrogen and phosphorous—which make the vegetation grow so well in our local fishing creek which receives the discharge that the fish are endangered by low oxygen content. Now we are taking part of this water out to the farmlands of the university where a truly interdisciplinary team of agronomists, foresters, hydrologists, and engineers are all working on the problem of putting the reclaimed water to good use.

Mr. MILLER. I think we are rather squeamish about this. People have to realize that sooner or later this water is going to be put back into the main.

Mr. CONABLE. This was one of the major theses of "Les Misérables" in Victor Hugo's discussion of the sewers of Paris.

Dr. BATES. In this case the top 10 to 20 inches of soil takes these chemicals out of the water and it returns to the water table in just as pure form as prior to initial usage.

Mr. MILLER. I notice in this same table about $18 million is spent on commercial fisheries and $7 million on sports fisheries and wildlife, That, of course, is more than matched by State funds, so the efforts in this field are much greater than indicated here; though, again, this is a cooperative effort with the Fish and Wildlife Service in each instance.

Mr. DADDARIO. Any further questions?

I want to thank you, Dr. Bates, and your colleagues for a very interesting morning. You have added a great deal to these hearings. We would like to have the opportunity to send some additional questions to you.[1]

Dr. BATES. I would like to thank the committee and say I have been tremendously impressed, at my first opportunity to appear before a congressional committee, with the concern of the committee, the way they have done their homework, and their real efforts here to move in a very important direction of major concern to the Nation.

Mr. DADDARIO. We are impressed, too, Dr. Bates, with the fact that people such as yourself come to Government after long experience in the academic field with such a wide breadth of knowledge and with concern about the problems of the Nation.

This is helpful to us beyond measure, and we appreciate it.

This committee will adjourn until tomorrow morning at the same place at 10 o'clock.

(Whereupon, at 11:20 a.m., the subcommittee was adjourned to reconvene at 10 a.m., Thursday, July 29, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

THURSDAY, JULY 29, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

Our first witness is Dr. Arnold Grobman, who is Director of the Biological Sciences Curriculum Study. We are pleased to have you, Dr. Grobman. I understand that Dr. Mayer is with you. It has been called to my attention that you have supplied us with a table full of books and other information which will be helpful to the committee. I would appreciate it if you would go right ahead with your statement.

STATEMENT OF DR. ARNOLD B. GROBMAN, DIRECTOR, BIOLOGICAL SCIENCES CURRICULUM STUDY

Dr. GROBMAN. Thank you. I have a prepared statement, Mr. Daddario, and I would like to read it and perhaps interpolate and omit some material as I go through it.

To examine the role of the National Science Foundation in developing and encouraging scientific education in this country and in promoting the advancement of scientific knowledge in general, it is useful to look at the state of science education before the Foundation came on the scene. My concern has been with curriculum improvement at the secondary school level so I will confine my remarks to that area, and specifically, to the development of materials for the biology curriculum.

How, then, has the content of the curriculum been established in America and has the National Science Foundation had an impact in improving the content? Has the NSF contributed to the goal of improving the scientific education of our citizens and the advancement of science generally? And how, from the point of view of science curriculum improvement, can the activities of the Foundation in this area be strengthened? It will be emphasized in this report that the NSF has made a singularly significant contribution to the improvement of science education through support of curriculum study groups but that much remains to be done. It will be emphasized in this report that the NSF has made a singularly sig-

nificant contribution to the improvement of science education through support of curriculum study groups but that much remains to be done.

Let us look back, then, on how content had been determined in our schools before the advent of the curriculum studies.

It is traditional to emphasize that in America control of education is at the local level with varying degrees of coordination through State departments of education. Close inspection of one aspect of education—high school science courses—leads to some instructive insights on how course content is, in fact, actually determined.

The local school board employs the science teachers and approves the selection of textbooks. But the board does not train the teachers nor does it write the textbooks. Although the local school board has considerable legal responsibility, the de facto determination of the actual content of science courses resides elsewhere.

The State departments of education establish criteria for the certification of teachers and could, in theory, determine the kinds of training teachers receive. In practice, however, the State departments legislate in terms of course credit hours and it is in the universities where determination of the actual content of teacher instruction is made. Some State departments of education do exercise modest control over the content of textbooks by prescribing to publishers. In almost half of the States, the education department periodically stipulates one or more textbooks which schools may purchase with State funds and thus it could influence the curriculum to the extent that there are real content differences of a substantial nature among competing science textbooks. But study of available textbooks—from the period before the curriculum studies—does not reveal substantial differences among textbooks insofar as basic content is concerned. On balance, since the training of the teachers is the responsibility of the colleges, and the writing of the textbooks is in the hands of authors and publishers, the control and influence on course content in the sciences by State departments of education appears to be relatively minor.

In theory, a high school science teacher has considerable freedom to determine the content of the courses he teaches. In practice, he teaches five, six, or seven classes a day for 5 days a week; grades the papers and reports of his students; arranges for his own laboratory materials and equipment; and is often obligated for certain extracurricular activities such as lunch room duty and monitoring study halls. Unlike his collegiate colleague, the typical high school teacher has an assigned workload so overwhelming that, regardless of his honest intentions, he must depend very heavily upon textbooks for determining the content of his courses.

Suffice it to say that the argument here is that the major control of content in science courses is through the textbook. So let's take a look at the textbook itself, and I begin by talking about publishers' roles.

In the initial plan for a new science textbook, the publisher and his authors design a book that is as educationally sound, up to date, and effective as they can make it. I have tremendous confidence in the integrity, competence, and ability of most American textbook publishers to produce educationally sound and stimulating books.

When such books are placed on the market, however, there develops an effective influence on, and actual control of, content for which no name seems to be available. I use here the phrase "content determination by the nonacademic marketplace" as a label to aid in examining this phenomenon.

The initially sound books placed on the market by the publisher bring him a variety of responses. One of the first is a series of negative reactions toward certain topics by small nonrepresentative groups in different parts of the Nation.

For example, the publisher of a good modern secondary school biology book is reminded, in one State, that his book would be quite acceptable if the topic of evolution were omitted because State law prohibits the teaching of evolution in the public schools. The publisher knows that the industry is highly competitive and that if he includes evolution in his book he will lose sales to competing publishers whose evolution-free books would be adopted instead of his.

In another part of the Nation, the same publisher is told that his biology book would be welcome except that the material on human reproduction "is a little too frank for our conservative community" and so he again faces the same kind of problem and usually arrives at the same nonacademic solution. In other communities, additional controversial topics meet resistance and on most occasions the publisher reacts by modifying or omitting sections of his book in order to try to satisfy most of the special interest groups. He continues to make downward adjustments in content in order to drive his sales record upward.

Relentlessly and predictably, in this fashion, a series of debilitating deletions is made by the publisher in his biology book. Resolutely this process continues despite the clear preference—subsequently demonstrated by the wholesale adoption of Biological Sciences Curriculum Study books—of the vast—and silent—majority of both informed lay citizens and educators for a sound scientific treatment of evolution, human reproduction, and other related biological topics, in a good high school biology textbook.

It should be underscored that the question I am trying to illuminate is not whether evolution or human reproduction or any other specific topic should be taught in high school biology classes. The question is whether such determinations of what is to be taught should properly result from the pressures of small, nonacademic, special interest groups. The end result of the process I have described is substandard educational materials for the Nation.

Returning now to the publisher, his initially excellent plans for a fine book, when molded by the actual and anticipated negative pressure of the nonacademic marketplace, frequently emerge as a lifeless compendium of factual statements without controversy, without vitality, and without interest. The various publishers' textbooks become safe, sterile, and similar and not in the interest of superior education. They are bland and colorless and the students who use them are largely unchallenged, uninterested, and unaffected.

Most informed people would agree that the scholars in a discipline, and the teachers of that discipline, should cooperatively have a major voice in recommending the appropriate content to be studied in our schools. Biologists and biology teachers should recommend

the model materials to be taught in biology classes; chemists and chemistry teachers, materials to be taught in chemistry classes; and mathematicians and mathematics teachers, materials to be taught in mathematics classes. In essence, this is the great contribution of the recent curriculum study groups, such as the Biological Sciences Curriculum Study (BSCS), the School Mathematics Study Group (SMSG), the Physical Science Study Committee (PSSC), and others.

They have brought together the teachers and scholars in their respective fields and those scholars and teachers have prepared model high school courses with content appropriate for our present day and age. In making the majority of these materials available to the schools with the full cooperation of textbook publishers, the curriculum study groups have been acting completely within the traditional framework of local control of education, our free enterprise system, and the fundamental tenets of our American democracy. And they have been able to overcome much of the negativeness of the nonacademic marketplace because NSF support has made it possible for the curriculum study groups to produce their materials independently of such pressures.

Mr. DADDARIO. Will you tie together that last statement, with the one on the previous page which says that the result of the nonacademic marketplace activity brings these books to the point where they are bland and colorless? Is this still the situation, or was this the situation before the NSF support allowed some advance in this area? Where are we at this stage of the game? Up to the point you made in the last statement I thought we were going completely by the least common denominator, but apparently there has been a thrust forward.

Dr. GROBMAN. The NSF support of the curriculum study groups has permitted us to write books that scientists and science teachers think are good and the publishers have published these unchanged because our contracts with the publishers state that they may not make any changes in these books. We feel that these represent very good educational materials and the schools adopt them very gladly.

Mr. CONABLE. How are you able to get the publishers to accept this?

Dr. GROBMAN. The way we have proceeded is fairly simple. We have announced to publishers that we have a manuscript available; we invite them all to bid on the manuscript; and one of the clauses in our contractual arrangement is that they may not make any changes. Of the existing textbook publishing houses, 20 houses have bid to produce our texts and we have selected 3.

Mr. DADDARIO. Do you find that because you have this contract with the publishers, that they will accept these books as written?

Dr. GROBMAN. Yes, they are being accepted. As I plan to mention later, the BSCS books are being very widely adopted.

Mr. CONABLE. But you are doing this with only 3 of the 20, and the pressures from the nonacademic marketplace must be the same as before. Is it simply the prestige of the National Science Foundation and your group that has been able to bring this about?

Dr. GROBMAN. Not the prestige of the NSF; I hope that is not the reason. The actual content of the books, I believe, is the chief factor. Teachers' committees look at them and study them and find that these are good books and they want to use them.

Mr. DADDARIO. Perhaps you are finding out, too, that these pressure groups were not as formidable as thought to be.

Dr. GROBMAN. Yes, the publishers would react to each small voice and bring the book down to that level. When we write our books as we think they should be written, these voices still arise occasionally but, nevertheless, the books are bought and used in the schools. Publishers have been unduly conservative, is another way of saying this.

Mr. CONABLE. Perhaps we should get the National Science Foundation interested in politics to discourage some of the pressure groups that work on us.

Mr. BROWN. Would you care to comment on how this phenomenon applies to other related fields? For example, it seems to me we might have a spectrum here in which pressure might be relatively less at one end, say, with mathematics or physics—maybe I am not picking good examples—relatively greater in biology and other areas, and perhaps the extreme is those areas dealing with the social sciences or even history. Is this, in fact, true?

In other words, does this phenomenon of the nonacademic marketplace affect all teaching at the high school level or some more than the others? You are giving us examples in the biological field.

Dr. GROBMAN. You have used words that I have often used in discussing this with colleagues. I think that the trend you describe is real. Nobody gets mad at a molecule. But some persons do become concerned with evolution and reproduction. They become even more concerned with political science, history, and humanities. I think, in biology, we are in a science that has moderate social implications in this sense, and it is a good experimental place for curriculum work of this sort.

Thus for many years conditions have been ripe for the design of science curriculums by scientists and science teachers. Probably most of the innovators did not analyze the educational scene in the terms of the sketch above; they simply began with the blunt and direct observation that our physics, chemistry, biology, and mathematics courses were demonstrably substandard and that we had ample resources to do far better.

The first of the modern curriculum studies in the sciences arose because of the clear insight, serious concern, and directed energy of Dr. Jerrold Zacharias of MIT. He was influential in obtaining support in 1956 from the National Science Foundation to establish, and later to bring to successful conclusion, the work of the Physical Science Study Committee which produced a modern course in physics—the first of a series of new senior high school science courses. Chemistry, biology, and earth science programs followed.

The program in biology—Biological Sciences Curriculum Study—began in 1959 under the sponsorship of the American Institute of Biological Sciences with financial support of the NSF. BSCS

policy is determined by a large steering committee whose members, on a rotating basis, represent university research biologists, high school biology teachers, school administrators, medical and agricultural educators, psychologists, educationists, and others.

The BSCS produced three alternative versions—some of our material is on the table, which I will be glad to leave with the committee for review at its convenience—of high school biology courses known as the blue, green, and yellow versions which provide teachers an opportunity to select a modern biology course most suitable to their local needs. Experimental editions of the versions were written during the summer of 1960 by a balanced team of 70 university and high school biologists. These experimental editions were tested by 100 teachers during the 1960–61 school year and, based on that experience, the books were completely rewritten during the summer of 1961. The second experimental edition of the three versions was then tested by 1,000 teachers and 150,000 students in 47 States during a 2-year period. This extensive testing led to the preparation of commercial editions by three different publishers and the books became generally available to the schools in September 1963.

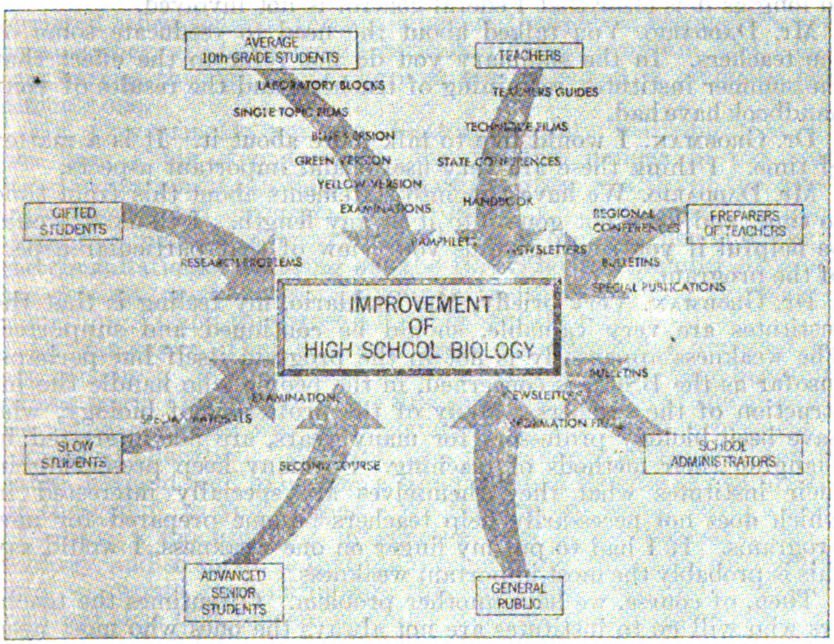
The commercially published books are extremely successful and are being widely adopted. About 700,000 students, of the 2,300,000 who were enrolled in 10th grade biology courses during the 1964–65 school year, studied from BSCS books. If present trends continue, the number should double in 2 years with a probability that BSCS books will be adopted by three-quarters of American high schools by 1968.

Of course, making these three versions of a biology textbook available for students to use was not sufficient. It was also necessary to assist teachers in their use of these new and different materials. So the BSCS prepared teachers' guides for each of the versions. Some biology teachers were found to be deficient in modern chemistry, physics, and mathematics and so the BSCS wrote a teachers' handbook covering these topics and many other aspects related to the improvement of biology teaching. Because of gaps in their early training, many teachers did not understand the use of certain modern laboratory techniques and, to attack this problem, the BSCS produced a series of films for teachers devoted to specific common laboratory methods. The BSCS also arranged a series of annual area clinics so that teachers using BSCS materials could review their procedures and problems with more experienced persons. As often as it was able to respond, the BSCS, in addition, assisted those responsible for summer institutes and school system workshops.

In a like manner, using normal commercial channels including eight different publishers, many supply companies, several film distributors, and others, the BSCS prepared supplementary laboratory blocks on selected topics to increase the flexibility of each course; a special course for slow learning students; research problems for gifted students; an advanced level course for high school seniors; supplementary single topic films to cover experiments impractical for the school laboratory; appropriate examinations for each of the courses; a series of booklets for those responsible for the training of biology teachers; lists of supplies and equipment for manufacturers

and suppliers; monographs on the history of biology teaching, working with gifted students in biology, and the design and administration of biology classrooms for school administrators; pamphlets on selected topics for teachers and students; and an information film and a series of newsletters for persons with both general and specific interest in the improvement of secondary school biological education. In addition, the BSCS has held regional conferences with educators and biologists responsible for the training of biology teachers; has conducted special orientation sessions for teachers in its experimental programs; and has arranged a very large number of conferences and committee meetings on specific topics contributing to the broad goals of the BSCS.

The BSCS is a multifaceted, total and continuing program. Its efforts are directed toward the improvement of biological education at the secondary school level which it does through the production of a wide variety of materials and through cooperation with virtually every group involved in the biological education of American secondary school students. (See accompanying diagram.)



The work of the BSCS has been financed by NSF grants totaling about $8 million through a 7-year period. During the same period, over $1 million has been earned through sales of experimental editions and through royalties on commercial editions. These moneys have been returned to the NSF for deposit with the U.S. Treasury. About 2,000 persons, other than students, have been involved in the development of BSCS materials. I am talking here about our domestic program and not our international program which I think should be another story.

Some summary statements about the BSCS could be made as follows:

1. It is the most intensive effort ever directed toward the improvement of a single course for American schools and has been highly successful.

2. It has used a scientific procedure; i.e., extensive school trials with rewritings, in the development of curriculums.

3. It has demonstrated that American high school students are capable of far more intellectual achievement than they are normally given credit for. I think this is a very important point.

4. It has shown that the majority of educational leaders at the local level prefer to offer their students modern substantive courses on which to chew rather than warmed-over pablum.

5. It has shown that American high school students, regardless of their individual career goals, have a real interest in understanding the processes of science—but not necessarily in the factual minutiae.

6. It has shown that those responsible for education at the local levels are glad to look to responsible national groups for guidance so long as it is clear that Federal control is not involved.

Mr. Daddario. You talked about the need to reeducate some of the teachers. In the summary you do not refer to the effect that the summer institutes, retraining of teachers, and the results of your handbook have had.

Dr. Grobman. I would like to talk more about it. It is a matter of time. I think these are very useful and important aspects.

Mr. Daddario. We have run into statements about this from time to time, and have not gone into it in any length. I think it would be helpful if you could give us your view of that particular aspect of the program.

Dr. Grobman. Very briefly, Mr. Daddario, my feeling is that the institutes are very valuable, should be continued and supported. The weakness apparently is not in the program itself but perhaps, insofar as the BSCS is concerned, in the people who handle the instruction of the teachers. Many of the professors of biology, who have been biology professors for many years, are not interested in changing their methods of teaching. So many keep presenting in their institutes what they themselves are specially interested in which does not necessarily help teachers become prepared for new programs. If I had to put my finger on one weakness, I would say this is probably the most important weakness.

Then, of course, we have another problem. Oftentimes the teachers who will go to institutes are not always the ones who most need the upgrading and training. Many willing teachers are unable to get to the institutes.

Mr. Daddario. You are appealing to the ones who are already pretty good and who want to improve themselves further?

Dr. Grobman. Often.

Mr. Daddario. I think the results have been indicative of great progress in this area. The type of teachers we can attract to teaching at that level is an important consideration for us to look into.

Dr. Grobman. Yes, I would think so.

Mr. Daddario. We have had occasion to talk to some of the people in the universities. They have often suggested that this is where a

great deal needs to be done. It is believed that with the right kind of programing, the right salary level and the building up of departments in the elementary and secondary school levels, that we could attract people with the desire to develop a teaching career.

Dr. GROBMAN. I think salaries are very important.

Mr. BROWN. Can I inquire at this point what effect this improvement in high school teaching is going to have? In other words, has this resulted in any shift upward in the quality of college teaching and in the quality of the biology teachers of the next generation?

Of course, it may be too early to observe this, but it is to be hoped that this would be so. I just wonder if you have any data on this.

Dr. GROBMAN. We have, yes, some information. We know that a number of schools, for instance at Berkeley, the students are now examined whether they have had a BSCS course or a traditional course. If they have had a BSCS course and do well on a little examination, they can move on to a sophomore course without taking freshman biology. A number of the colleges are doing this but not enough, I am afraid.

I believe the problems that you are talking about will in part be obviated when some of these youngsters themselves become teachers, because they will have had an entirely different program, and I hope this carries through. But the changeover period is going to be a difficult one.

Mr. CONABLE. Do you see, Doctor, possibly realizing that this has been a big step forward, any possible danger in too much standardization in this field? One of the great wealths of the American educational program is its diversity. You must be going through a process of arriving at the least common denominator in the consultations that bring out the BSCS book, a number of people are getting together and resolving their differences and agreeing on something. Can't this process itself be stultifying?

Dr. GROBMAN. That is a very good question and I am glad you are raising it. We have been aware of this from the very beginning of our work. In fact, when we first got together, one of the questions we asked ourselves was what could we do for the improvement of biological education. We said, let's not write a single textbook because it would tend to become a standard item because of the prestige of the group, as you suggest. We thought we would write a series of units, a modern unit in genetics, one in biochemistry, one in ecology, and so forth, so that the teacher could design his own courses and we would thus encourage this desirable flexibility. We soon realized that that scheme wouldn't work because most teachers, you know, teach six or seven classes a day, 5 days a week; monitor a study hall; have lunchroom duty; and so most of them simply can't design their own courses from resource materials. So we finally decided to produce several different kinds of biology books, and that accounts for the three versions I mentioned. In addition to each one of these three versions being quite different from each other in approach, each is quite flexible in that each contains twice as many laboratory exercises as could possibly be completed in the course of a year, so the teacher can pick and choose what he would like to teach. Then, as supplements, we produced the laboratory blocks with which the teacher can enrich his course. Thus we end up with

a very large number of offerings with these basic materials. We have been very much aware of the question you raised and furthermore we encourage—I do any time I get a chance—teachers to use any materials they want, not just BSCS materials, so we are not trying to "sell" one single kind of course.

Mr. DADDARIO. You are trying to establish a higher level to begin with, and give them the building blocks to go from there at whatever speed they feel they are capable.

Dr. GROBMAN. That is right. I have used slightly different words: we are trying to prepare model materials and we hope others will build on our materials or use them as examples. If we arrive at the stage where materials produced by others are superior to ours, we would be delighted to get out of business. That hasn't happened yet.

The National Science Foundation contribution to the welfare of American education, through support of the curriculum studies and institutes for teachers, cannot be overestimated. American education, with its record of rich potentialities which have been largely unfulfilled for generations, has been stimulated by NSF support into a course content improvement activity of tremendous value. From this stimulation, course improvement promises to continue and is already expanding into fields outside of the sciences. It is heartening to note that other specialists are beginning to prepare materials designed to be competitive with those of the curriculum study groups.

The NSF leadership has had the wisdom and the courage to support the development of curriculum studies when they were in their early formative stages—when they were simply ideas in the minds of a few forward-looking planners. The curriculum studies could never have developed to present productive stages without the sympathetic support provided by the NSF.

The NSF has used its good offices to arrange for scholars and leaders in various disciplines to become acquainted with each other's work thus contributing to the general effectiveness of all participants.

The NSF fiscal officers and their supervisors, while properly giving first concern to a conservative and effective use of public moneys, have been unusually helpful to the academic people involved in the curriculum projects who, often, do not have firsthand familiarity with governmental agency procedures.

Valuable suggestions for improvement of study programs have come from NSF personnel who have been responsible for the review of early proposals by curriculum study groups.

The NSF has shown good judgment in the support it has given to the curriculum study groups. American students and teachers will profit for generations to come. There is no question that the national welfare has benefited very greatly through NSF sponsorship of the curriculum improvement movement.

Now, I go into a few details about the BSCS relationship with NSF.

During recent years, negotiations between the Biological Sciences Curriculum Study and the National Science Foundation have become increasingly difficult. Perhaps the major reason for this is that the Biological Sciences Curriculum Study is pioneering in its curriculum work and is at the growing edge of many new programs.

For example, it is the first of the curriculum groups to be concerned with a thorough and complete revision of its textbooks. It is one of the few groups that sees the need to extend its developmental work. The Biological Sciences Curriculum Study steering committee has made firm plans to continue to contribute to the improvement of biological education whereas some of the other curriculum groups are satisfied to consider their work completed when they have produced a set of new course materials for their fields. These goals of the Biological Sciences Curriculum Study create complex problems for the National Science Foundation since policy guidelines do not now exist for the handling of many unanticipated questions that constantly arise.

The difficulties that have developed can, perhaps, be subsumed under a few headings. Further details are included in an attached appendix which is a memorandum I have recently submitted to the Biological Sciences Curriculum Study steering committee.

(1) Lengthy periods of National Science Foundation indecision have adversely affected the Biological Sciences Curriculum Study program.

(2) The National Science Foundation has awarded grants for short—and variable—periods which have mitigated against well-organized planning on the part of the Biological Sciences Curriculum Study.

(3) In recent years, the National Science Foundation has consistently awarded grants at the last possible moment, which procedure has adversely affected the orderly administration of the Biological Sciences Curriculum Study.

(4) National Science Foundation officials have improperly interfered with the internal operations of the Biological Sciences Curriculum Study and, upon occasion, have been needlessly restrictive.

(5) The National Science Foundation has acted adversely on grant proposals of the Biological Sciences Curriculum Study, upon the recommendation of external reviewers, without providing opportunities for discussions, either directly or indirectly, between the reviewers and the Biological Sciences Curriculum Study.

(6) The policymaking body for the National Science Foundation has not taken full advantage of the considerable experiences of National Science Foundation grantees.

(7) The National Science Foundation exercises undue policy control through its fiscal control.

In summary, I should like to make the following remarks.

The National Science Foundation support of curriculum study groups has greatly enhanced science education in this Nation. Such sponsorship of the Biological Sciences Curriculum Study, for example, has already brought about an unprecedented revolution in biological education. As a result, high school students are developing understandings and proficiencies in biology beyond all prior reasonable expectations.

In many ways, National Science Foundation has exercised good judgment. The tremendous benefit to America of National Science Foundation contributions to science education, through support of the curriculum study groups, is incalcuable.

But the National Science Foundation does not now seem to be adequately responsive to further developments, particularly by groups pioneering new activities. In Biological Sciences Curriculum Study experience, National Science Foundation appears to be slow to act, indecisive, late in awarding grants, and unfortunately unaware of the role it must play in the continuation of curriculum improvement.

The tremendous momentum that has been achieved in the improvement of science education through National Science Foundation stimulation is destined to falter unless the Foundation can begin to meet the challenges before it far more effectively.

(Appendix to Dr. Grobman's prepared statement follows:)

MEMORANDUM No. 217

BIOLOGICAL SCIENCES CURRICULUM STUDY,
UNIVERSITY OF COLORADO,
Boulder, Colo., June 14, 1965.

To: Biological Sciences Curriculum Study steering committee: Glass, chairman, Andrews, d'Arc, Arnon, Auffenberg, Boyce, Brain, Cheadle, Hurd, Jordan, Kennedy, Kolb, Larsen, Lee, Magoun, Mayer, Moore, Palmer, Rollins, Welch, Went, Williamson, and Wolfson.
New members, October 1, 1965: Liebherr, Moog, Olsen, Phillips, Read, Rohrbaugh, and Rosen.
Biological Sciences Curriculum Study committee chairmen and writing team supervisors: Hastings, Peterson, Schwab, and Snider.
AIBS: Kennedy, Olive, and Thimann.
CUEBS: Greulach and Hall.
UC: Smiley and Wilson.
NSF: Dees, Haworth, Hemily, Kelson, Mays, Paulson, Riecken, Roe, Whitmer, and Wilson.

From: Arnold B. Grobman, director.

Attached is a copy of a memorandum I sent to the Biological Sciences Curriculum Study executive committee on June 11.

BIOLOGICAL SCIENCES CURRICULUM STUDY,
UNIVERSITY OF COLORADO,
Boulder, Colo., June 11, 1965.

Memorandum to: Biological Sciences Curriculum Study executive committee: Glass (chairman), Mayer, Moore, Palmer, and Rollins.

From: Arnold Grobman.

Please consider this memorandum notice of my resignation as director of the Biological Sciences Curriculum Study to take effect on September 1, 1965.

I have accepted the position of dean of the College of Arts and Sciences of the Men's College at Rutgers University.

The opportunities for me at Rutgers are of no special interest to the welfare of the Biological Sciences Curriculum Study, but the reasons why I would be willing to leave the directorship of the Biological Sciences Curriculum Study, at a time when the study is enjoying such remarkable success, should be a matter of concern to the Biological Sciences Curriculum Study executive committee.

The remainder of this memorandum, therefore, will be devoted to those factors which have made the directorship of the Biological Sciences Curriculum Study increasingly untenable for me, I realize that some of these points may have implications for the national welfare, beyond the Biological Sciences Curriculum Study program, but my sole concern here is exclusively with the Biological Sciences Curriculum Study. I hope to contribute to an amelioration of some of the problems I perceive by bringing them to your attention through this document.

BACKGROUND

The Biological Sciences Curriculum Study has developed into an entirely new kind of organization for which there seems to be no name available. Some day, Biological Sciences Curriculum Study-type organizations will take their place, along with schools, colleges, State education departments, textbook publishing houses, and boards of education, as necessary partners in the American education movement. Essentially the Biological Sciences Curriculum Study has become a service contributing in a total way to the improvement of biological education at the secondary school level. For 10th-grade students (the level at which biology is normally taught), the Biological Sciences Curriculum Study has produced three alternate basic courses with tremendous flexibility provided through laboratory blocks, single topic films, and supplementary exercises. For gifted students, it has produced four volumes of research problems and for low-ability students a special course is now nearing completion. A program titled "The Interaction of Experiments and Ideas," was recently published for students selecting a second course in biology (usually at the 12th grade). A complete testing program has been designed for all of these students and consideration is being given to the development of a new college entrance examination in biology. For teachers of biology there are now available, through Biological Sciences Curriculum Study efforts, recommendations on equipment and supplies, guides to the versions, a teacher's handbook, films on laboratory techniques, a series of subject matter pamphlets, and an annual series of State-by-State conferences. For those responsible for the training of teachers, both within the school systems and on the college campuses, the Biological Sciences Curriculum Study has produced a series of special publications; has participated in many institute training programs; and is planning a series of films on teacher preparation for Biological Sciences Curriculum Study biology. For administrators and others concerned with the environment in which secondary school biology should be taught, the Biological Sciences Curriculum Study has published three bulletins dealing with the developmental history of secondary school biology as well as with the design and structure of high school biology laboratories. For all these persons, as well as for others with an interest in biological education, the Biological Sciences Curriculum Study has prepared an informational film about the Biological Sciences Curriculum Study as well as a continuing series of periodic newsletters. Through these various avenues, as well as through nonacademic agencies (textbook publishers, equipment manufacturers, and film distributors), the Biological Sciences Curriculum Study is having a multiple-pronged impact on the improvement of biological education at the secondary school level. This is a virtually unique breakthrough in the improvement of education in America and deserves the fullest encouragement possible until its full impact can be adequately assessed.

There have been a multiplicity of collateral benefits accruing from the activities of the Biological Sciences Curriculum Study. Perhaps the simplest way to indicate some of these would be by referring to the real and meaningful communication channels that have been widened between university and college biologists and biology teachers, science supervisors, principals, superintendents, professors of education, testing specialists, science educators, curriculum specialists, equipment designers, textbook editors, and many others.

The impact of the materials can be indicated by pointing out that the basic versions are currently being taught to about 700,000 students and every time four schools adopt a new biology book, three of them select a Biological Sciences Curriculum Study version.

Nor are the effects of the work of the Biological Sciences Curriculum Study limited to the United States, Specific adaptations of the basic courses to the local fauna, flora, and educational systems (not merely translations) are currently being prepared by teams of biological colleagues in Argentina, Australia, Brazil, Canada (French), Colombia, Israel, Italy, Japan, New Zealand, Philippines, Taiwan, and Thailand. Special instructional sessions have been held, in addition, in Ceylon, Denmark, England, Guatemala, India, Mexico, Peru, Turkey, and Venezuela.

PROBLEM OF BUDGET PERIODS

Through the short (six and a half years) history of the BSCS, we have had to work, at one time or another, with 4-month, 5-month, 6-month, 8-month, 12-month and 15-month budget periods, each at the direction of the National Science Foundation which provides our major financial support. Rational planning based on comparable fiscal studies is virtually precluded. The shorter budget periods make for almost impossible administration.

PROBLEM OF TIMING OF GRANTS

Our proposals to the National Science Foundation for support of the BSCS have normally been submitted about 4 months before they were due to take effect but grants have not been awarded on schedule. For example, our proposal for support for the calendar fiscal year 1965 was submitted to the NSF in August 1964. Pursuant to this proposal a grant for a 4-month period was made by the NSF on December 28, 1964, 3 days before the start of the new fiscal year. A revised proposal was required for the remaining 8-month period starting May 1, 1965. A letter extending the grant period to December 31, 1965, was received from the NSF on May 11, 1965, 10 days after the fiscal period had started and grant funds were awarded for only 2 months. Presumably further funds will be made available about July 1 for the last 6 months of 1965. Virtually all grants to BSCS, in response to proposals, have followed patterns similar to that outlined above. Of eight major NSF grants, under which the BSCS has been financed, seven were awarded less than 1 month prior to the scheduled due date and, of these seven, three were actually awarded after the due date. It is virtually impossible to operate an on going program under such conditions.

PROBLEM OF INTERFERENCE IN INTERNAL OPERATIONS

It is, of course, axiomatic that the NSF must be kept fully informed about the expenditures of funds made available through its grants. Honest differences among men of good intent will certainly arise in defining the boundary between proper control of grant funds by the NSF and unwarranted interference in the internal affairs of the grantee by the Foundation. I believe that the Foundation has erred frequently on the side of interfering in matters that are internal BSCS responsibility. For brevity, I will simply identify a few examples here without full discussion.

In 1962, after the AIBS mismanagement came to light and without consulting the BSCS, the NSF transferred management of the BSCS to the University of Colorado. Whether this was the best of several solutions possible at the time is irrelevant to the matter of the unilateral action taken by NSF.

Shortly afterward, without discussing any of the details with BSCS, the NSF, AIBS and the university entered into a tripartite agreement under which assignments of the copyrights of books written by BSCS authors were made without including the BSCS.

It was the considered opinion of the BSCS (with which opinion the publishers agreed) that the revision of the versions should begin in the summer of 1965 for publication in 1967. Unilaterally, and despite a special appeal from the BSCS, the NSF decided that this was too early and, as a result, would not support revisions for this summer.

The United States-Japan Committee on Scientific Cooperation, Panel on Education in the Sciences, in 1964 approved a joint program to be held in Tokyo in 1965 devoted to a revision and adaptation to Japanese conditions of the BSCS blue version biology textbook and laboratory manual and to a study of the Japanese Science Education Centers for the renewal of training of secondary school science teachers with a view to their applicability to American education. In spite of the fact that much of the planning for the joint writing conference in Tokyo was initiated by the BSCS, and involved BSCS personnel and policies, the BSCS was excluded from any direct participation in the operation of the joint study other than to nominate two persons to represent the U.S. participation.

PROBLEM OF PERSONNEL

Frequent remarks by NSF staff members on the question of "phasing out" of the BSCS now "that its work is done" have had demoralizing effects on the BSCS staff. Many members of the staff are hesitant to commit themselves for more than a year's service and at least one man has resigned to accept a post with a publishing house at a most substantial reduction in salary. His primary reason for leaving was to avoid uncertainty in continuity of employment; he wanted to be in one place long enough for his children to complete high school without moving.

Other remarks by NSF staff, to the effect that "the BSCS is being run by the same small handfull of people," has caused the BSCS executive committee to adopt a very stringent rotation policy. Rotation of policymaking personnel and professional staff members is desirable, within limits, because new ideas are thus brought to the BSCS (and, conversely, the BSCS developments are introduced to wider audiences) and the staff and committees enjoy continuing intellectual stimulation. Except for the chairman, there has been 100-percent turnover of steering committee members since rotation was initiated in 1961. More significant, and quite distressing, is the disruption caused within the professional staff through this policy. Of the eight full-time academic persons currently on the staff only one will remain a member of the staff after September 1. Nor is this an exceptional year.

The tremendous burden placed on the director in continually recruiting able and specialized personnel, and annually orienting new staff members to their complex responsibilities, need simply be mentioned to be appreciated. In addition, the lack of continuity in staff member contracts with persons outside the study has thrown more and more of this kind of responsibility on the director. I am convinced that the BSCS suffers very seriously because of the lack of staff continuity resulting, in large part, from NSF indecision and thinking out loud. At the very least, the BSCS is adversely affected because the time of the director is usurped so that he is unable to use opportunities to perform at higher levels.

PROBLEM OF MANAGEMENT

The transfer by NSF of fiscal management of BSCS from AIBS to the University of Colorado in November 1962 was regarded by all concerned as a temporary measure. To assist in reaching a solution to this difficult problem, the BSCS has made two positive recommendations for NSF's consideration: Management by an existing private educational institution or management through a corporation whose members would be a group of colleges and universities. The feasibility of these two approaches has been fully explored by the BSCS. The BSCS also invited the AIBS executive committee, which wishes to resume management of BSCS, to describe its plans to the members of the BSCS steering committee. In October 1964 after a full meeting and discussion between the two groups, the BSCS steering committee met separately and voted unanimously against the resumption of management of BSCS by AIBS at this time. To these three recommendations, the NSF's reply is that it is studying the matter. Two recent letters to NSF officials on these management matters remain unanswered. In the meanwhile, two and a half years have passed and we seem to be no closer to a solution of the BSCS management problem than we were in late 1962.

PROBLEM OF PROPOSAL REVIEWS

The method of appraisal of BSCS proposals seems completely inadequate. The proposals, which are complex and have involved more than $1 million annually, are reviewed by referees and NSF staff. Reviewers appear to be largely unfamiliar with the activities of the BSCS but there seems to be little hesitation, on the part of the NSF, to delete budget items (e.g., revision writing conferences for the summer of 1965) on the recommendation of such reviewers. The director of the BSCS has never had an opportunity to discuss the BSCS program with a panel of reviewers nor to demonstrate BSCS facilities through a site visit by a panel of reviewers.

SUMMARY

The situations alluded to above, and the implications that follow directly from them, as well as many other aspects of our present operations over which I have no adequate control, have combined to make the position of director of the BSCS increasingly untenable for me. I hope that my resignation will stimulate corrective measures.

THE FUTURE

The long range promise of service by BSCS to biological education is obvious to all who are familiar with the study. We need to continue our current programs and extend our international activities; we should plan for a very substantial revision of our versions so that they will continue to be both challenging and modern and will not simply become a new orthodoxy; and we must prepare to participate in extension of our efforts into the junior high school.

Rather than discussing such long-range plans, I will simply refer here to some items of immediate importance for the executive committee.

With the exception of the directorship, and two responsibilities discussed below, the staff for next year has been recruited and is of high quality; it promises to be one of the best staffs the BSCS has ever had. I have not been able to find a person to assume the responsibilities for the evaluation program and, as a substitution, I am exploring the possibility of contracting with an outside responsible agency for this service. I have not yet hired a person for public information services but I do not think that this will be a serious problem.

The 1965 budget is approved and funds are at hand for operations through June 1965, with additional funds for the last half of 1965 anticipated shortly after July 1, 1965.

Only preliminary work has been started on the proposal for 1966; I believe the proposed budget should remain fluid until the new director is appointed.

Please be assured that I will be happy to contribute, in any way I can, to a smooth transition of the directorship. I stand ready to devote my full efforts to this end prior to September 1, 1965, and all the time I can possibly spare after that date.

Each of you knows me well enough to appreciate how reluctant I am to send this memorandum to you. We have shared, with ourselves and with many others, the fine successes the BSCS has enjoyed and we have shared, alone and without rancor, the failures as well. These six and a half years have been tremendously exciting and rewarding and I shall ever be in debt to the members of the executive committee for the encouragement they have given me.

Mr. DADDARIO. Dr. Grobman, have you, in the appendix to your statement, covered some of these points in broader detail?

Dr. GROBMAN. That is right.

Mr. DADDARIO. I think it might be helpful if you could go into some of this from the standpoint of pinpointing it more precisely. We recognize the problems of continuity of budget support.

What do you believe the situation is at the moment? What more can be accomplished? What needs to be done? How can the NSF play a better role? What are the lines of communication between you? What do you see as the means which are available to help?

You have a pioneer program, here. Mr. Brown has alluded to possibilities in many other areas, where similar programs would be of assistance. I think your observations would be of immense value to this committee.

Dr. GROBMAN. That is a difficult question.

The problems arise, as we move in new areas—let's take one example; maybe it will help to have a concrete example. The books we have written were published in 1963, and we felt it was time to have the books revised this summer. Now, by revising them this

summer, that means they would be available in 1967, because it takes that long to get the manuscripts prepared and printed, especially when we work primarily in the summers as we bring people in during vacation periods. So in our proposal to NSF, which we wrote in August of 1964 to include work for the summer of 1965, we included a request for funds to prepare the revisions. I understood that the proposal was submitted to external reviewers and they said, "Well, the books were written in 1963 and here they want to revise them in 1965; that is much too soon," so NSF declined to grant funds to us.

Well, we have had a long correspondence, and I have brought samples along to leave, if you like, about this question of revision. The correspondence now indicates that the NSF didn't understand why we wanted to revise the books.

Well, I can hardly believe that is the case. If the external reviewers said to the NSF, "It is too early," I would have been glad to have someone from BSCS talk with the NSF and the reviewers to try to demonstrate that it isn't too early. It is a normal cycle, in publishing, to revise books on a 3-, 4-, or 5-year cycle. We were aiming at an average cycle. But there was just a loss of communication, and the loss of communication was, in my eyes, due to the fact that the BSCS wasn't permitted to become involved in the considerations of its proposal.

I get the feeling sometimes that we are being treated as a property, rather than as people. And I also have the feeling that sometimes the NSF scientists and academic people, with whom we work, will concur with us on our problems and proposed solutions but then, somewhere along the line, they are overruled by either their legal or fiscal people and roadblocks are thrown in the path of the progress we would like to make.

I don't know what the solution is to this problem. I fully understand that there must be fiscal and legal control, naturally. The solution must lie within the NSF including the problem of effective communication with the grantee.

Another example concerns the copyrights on our books. The arrangements for the copyrights are among the NSF, the American Institute of Biological Sciences and the University of Colorado. But the BSCS is not permitted by this triumvirate to have a role to play in the copyrights and, after all, the BSCS is actually the collection of people who wrote the books; they should obviously be involved in the copyrights.

Maybe another way of saying this, Mr. Daddario, is that there are two main components to the production of these textbooks. One is an intellectual component, which the BSCS has contributed, and the other is the fiscal component, which NSF has contributed. Both should be represented in the control and the administration of these materials, and not just the fiscal interests alone.

Mr. DADDARIO. You see conflicts in here of an unresolved nature, obviously?

Dr. GROBMAN. Yes. So far. I have no recommendations as to how to solve this, but it is a very serious matter to us, of course.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have no immediate question. I would like to come back a bit later.

Mr. BROWN. I am quite interested in the problems which you have cited here. I particularly am interested in whether or not this is an indication that there may be alternative ways of handling this overall educational job of curriculum improvement, other than what we have been doing.

Specifically, I would like to inquire as to the rationale why a broad program of curriculum improvement for the high schools of this country necessarily is best supported by the National Science Foundation rather than, say, the Office of Education, which is presumably responsible for the Federal Government's role in education on a much broader basis. Furthermore, is there any reason why the efforts at curriculum improvement need to be limited to biology, or the sciences, or any other one area? Are, in fact, efforts being made in other areas to parallel the efforts made in biology? And, if so, where do we draw the line between what will be done under NSF sponsorship and what will be done under Office of Education sponsorship?

Dr. GROBMAN. I think part of this is historical, Mr. Brown. When the NSF began functioning, you will remember, it first started supporting research workers, and then helping teachers with summer institutes, and then the curriculum studies. In those earlier days the Office of Education was not nearly as large and vigorous an organization as it is getting to be now. It does now support curriculum projects, and I believe there is a mechanism between the NSF and the Office of Education to see which projects are more appropriate for each agency. There are many curriculum projects going on in English and history and in social studies, oftentimes supported by Carnegie or Ford Foundation or some other private source. But the best work has been done in the sciences, in part because of the point you raised earlier. You remember, we talked about the fact that the physical sciences have less emotional connotations? For this reason, science is a good place to pioneer in curriculum improvement. I think we can get at the basic problems, without certain kinds of emotions being raised, by investigating science curriculum improvement first, and this may give us clues as to how to proceed in other areas.

I would like to see the NSF encouraged to continue in this area and, using this experience, to have more curriculum work done in other fields, perhaps under some other agency.

Mr. BROWN. The basic mandate of NSF is to strengthen basic research in science. The tool of curriculum development is merely a tool toward the ultimate strengthening our our basic scientific research resources in this country. It seems to me that we are growing closer and closer to the situation where NSF is undertaking general support of education when it gets to the point of modification and improvement of curriculum. This expands from one area of science to many areas of science, and to areas on the fringes of science. I wonder—and I do not think we will resolve it here this morning—whether we need to take a broad look at this in terms of strengthening our whole basic structure of education at the elementary and secondary level. Do it as a means of improving the quality of our society and not

purely in terms of an adjunct to the strengthening of basic research in the physical sciences, which is the way it is developing at the present time.

Dr. GROBMAN. I would like to make two remarks in response, if I might.

First, to strengthen basic science, we really need to have better science courses in the schools, because otherwise we lose the interest of youngsters in science even before they enter college. So this could be considered—what is the term you use here—a mission goal: curriculum improvement in science. But then I agree with your further point, which I think would be a very useful thing for this country to engage in, to support curriculum studies of this nature across the board. This should not be under NSF, and it should be under some other more representative body.

Mr. DADDARIO. Will the gentleman yield?

Mr. BROWN. Certainly.

Mr. DADDARIO. There is some curriculum study going on in the Office of Education. The point is raised that it ought not to be in just one agency because there ought to be some competitive aspects and diversity to this.

I think Mr. Brown's point is an extremely important one from the standpoint of what this committee finally recommends. It would be helpful if you could go into Mr. Brown's question in a little depth. What are these competitive aspects, and the importance of diversification?

Dr. GROBMAN. I am not too sure I understand the question.

Mr. DADDARIO. Should NSF be in it, at all?

Dr. GROBMAN. Oh, yes.

Mr. DADDARIO. I think this goes to the heart of Mr. Brown's question.

Dr. GROBMAN. I think NSF should not only be in it, but be in it more strongly until there is some other way of handling this broad problem.

Mr. DADDARIO. You have been involved with this for some time. What other ways are available?

Where do we go from there? I think this program of yours is running into difficulties because of the points which Mr. Brown has raised.

Dr. GROBMAN. It is running into difficulties, you can say it that way. You can say it is so because the NSF is not being flexible enough, which, I suppose, relates to the problem. I don't know the answer. I think what you are asking for is a long-range solution. I have brought to your attention what is a relatively short-range problem. The long-range solution certainly should involve the total support of curriculum studies by the Government in some other agency than NSF, but I don't see what the agency would be, right now. The Office of Education has not yet had a history that would give one confidence in its supporting this well; maybe it could have such a direction in the future.

Right now I wouldn't personally be enthusiastic about such a home for general support. I agree, further, that it should not be left to the private foundations, alone, because they can come in and

withdraw as they will, and this could be contrary to the national welfare.

I am not too worried about the question of diversity if the supporting agency has multiple supporting funds so it can sponsor several curriculum groups or one large one that has good representation from many people in the field. I have oft-times thought that one way to handle this might be to have a presidential adviser on education, outside of the Cabinet. But this would not be a way of financing curriculum studies, but rather making educational information available to the local schools and local school boards.

I suppose on balance, the best home for support of curriculum studies would be the Office of Education, but I am not now enthusiastic about it.

Mr. DADDARIO. You feel because NSF has made the start that it should perhaps continue and expand at this time. When the Office of Education has reached the point where it can take it over, we should reexamine NSF's role?

Dr. GROBMAN. I would go just a touch further than that, Mr. Daddario. I would say that the NSF should not only continue but should be encouraged to proceed further because it is supporting models for curriculum design and improvement. It happens to be doing so in the sciences. I think we have got a lot to learn from what the NSF is doing, and the curriculum projects it supports, as to how we might want to move in the future with broader projects.

Mr. BROWN. How broad is the NSF support in the sciences? What progress has been made in fields other than biology, just very briefly?

Dr. GROBMAN. Very early there was a program in mathematics, supported by Carnegie, and the NSF has subsequently been supporting that study. Large NSF support involves mathematics, physics, chemistry, anthropology, and earth sciences curriculum studies at the high school level.

Mr. BROWN. Have they resulted in this type of BSCS books?

Dr. GROBMAN. None of them as extensive, but the physics program has resulted in a book and many supporting films. There are two chemistry programs. They have all, I think, been very good programs.

Mr. BROWN. Has the model or method of support been similar to the one in biology? In other words, has NSF provided funds under a contract arrangement with a group such as the American Institute of Biological Sciences, or a similar organization which has actually done the work?

Dr. GROBMAN. Yes. It is through a grant arrangement rather than a contract arrangement, and usually to a university or a group of scholars.

Mr. BROWN. Are these arrangements as broadly based as in biology?

Dr. GROBMAN. No, I would think ours are a little broader in terms of the products, because we have tried to do many more things. Most of the others have limited their interest primarily to designing a course and the related materials, and have stopped there.

Mr. BROWN. The thing that worries me is not the specific administrative location of a program for funding a particular curriculum

development project, but whether or not there is in some location an overall responsibility to see that there are no gaps left of any significance. There should be a general upgrading of curriculum so we don't have in one school a tremedously effective biology course and a ridiculously ineffective course in history or something of that sort. If there is a responsibility of this overall nature, I don't think it makes too much difference whether NSF continues to take a segment of this and some other organization takes another segment, or private foundations take a piece of it. We will get the job done, and it may be better to have it done in a diversity of ways. But I don't see at the present time where this overall responsibility lies, and maybe we haven't recognized it yet.

Dr. GROBMAN. I agree with that, completely. The overall responsibility now rests in the hands of local school boards—they can select what they like to use—or in the State departments of education, or the teachers or the principals.

I do think that we need some kind of good answer to your question. What we are doing now in these curriculum studies is building better blocks, but no one has shown us how to build an edifice out of these blocks. We need some kind of architectural structure. It shouldn't be from the Office of Education, because this obviously would be so confused with Federal control in the minds of the people that it would be a very difficult thing. We do need some kind of recommendations as to which are the best arrays, the best because of experience and teaching, the best arrays of courses to use in a particular kinds of situations. Yes, I think you are right.

Mr. BROWN. Is there any particular reason, other than historical, as to why the support for this program in biology comes from NSF rather than NIH?

Dr. GROBMAN. The NSF was in the curriculum improvement support business, and when we got started, I guess it was the only source we knew about. I don't know of any NIH support of curriculum study at the high school level. There may be, but I don't know of any.

Mr. BROWN. No further questions.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. Is the concern about possible control in HEW a concern of yours, or a concern about the possibility of misinterpretations of control of curriculum improvement?

Dr. GROBMAN. Do you mean broadly, or just for our program?

Mr. CONABLE. You mentioned that too much curriculum control from HEW might be interpreted as Federal control with all its undesirable implications.

Dr. GROBMAN. I am not worried about that, because I think the Office of Education and the NSF are capable of divorcing themselves from this and letting the content be strictly in the hands of the writers, but it would be awfully difficult for school people to understand this. It would just be a very difficult thing to explain, and they wouldn't see the situation clearly.

Mr. CONABLE. Maybe this is a matter of curiosity more than anything else. You have said roughly a third of the biology courses in the country now being taught are using your materials. Can you

generalize about the geographical distribution of the acceptance of your program?

Dr. GROBMAN. Well, it is nationwide. There isn't any real—well, there are a few weak areas. It is a bit slower in the South, and in part that is because many of the Southern States have a State textbook adoption program in which a State commission will adopt books for the whole State, and they will do this only once every 5 years, and many of these 5-year adoptions haven't come up as yet.

It is a little slower in New England. I suppose that is perhaps because of some conservatism there, and it is a little slow in New York. I am sure this is because of the regents exams and the people in Albany who have decided that they want students to prepare for the regents, but the regents haven't followed these programs, as yet.

Mr. CONABLE. But you don't draw any unhappy conclusions from these weak spots? It is just a matter of time, probably?

Dr. GROBMAN. Well, of course, these people would say they are not weak spots.

Mr. CONABLE. I understand, but from your point of view, they are?

Dr. GROBMAN. Yes.

Mr. CONABLE. But you are confident. I believe you have said that three-quarters of the schools in the country will be using the BSCS materials?

Dr. GROBMAN. By 1968, if the present rate of adoption continues.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I notice with interest on page 11 of your remarks that you quote an estimated dollar figure of about $8 million with roughly $1 million return. I would gather the $1 million return will probably increase through sales and royalties?

Dr. GROBMAN. Yes.

Mr. VIVIAN. Over a period of time, this may all be returned?

Dr. GROBMAN. I don't think so.

Mr. VIVIAN. Or some larger fraction?

Dr. GROBMAN. Certainly a larger fraction.

Mr. VIVIAN. Supposing I were to estimate the total amount of money spent on the preparation of textbooks in comparable work over the last few years within the commercial enterprise; would it be comparable?

Dr. GROBMAN. It would be negligible, compared to these figures.

Mr. VIVIAN. In other words, it is not so much a question of shifting the financing of textbook preparation from an established pattern of commercial enterprise through their typical fees to authors and royalties and so on, but of increasing the scope and level of textbook effort by a significant amount in the field?

Dr. GROBMAN. I would say that, but there is also one other point, which I think is a key factor. When publishers prepare textbooks, they are scarcely written by high school authors. They are called in-house preparations. They are written inside the publisher's office by his editors. There are authors, of course, but they don't contribute the substantial amount when they do, and the publisher says, "Look, Joe, this won't sell, we know from our market experience"—the publisher greatly influences the product that comes out. This is unfortunate for American education. I think, rather than the

quantity of work, that the real contribution of the curriculum studies, at least in biology, is that they have been able to produce books representing the thinking of the scientists and the science educators rather than the thinking of what the publisher feels he can sell.

Mr. VIVIAN. How does the publisher introduce new material?

Dr. GROBMAN. You mean before the advent of the studies?

Mr. VIVIAN. Yes.

Dr. GROBMAN. The publisher's books are quite up to date. The latest things are in them, and they are carefully studied so that everything is accurate, and there is nothing factually wrong but the books are dull little encyclopedias and the kids aren't interested in them. The publisher has reviewers, but he also is controlled by this other factor (non academic marketplace control) I have been trying to describe, perhaps before you walked in.

Mr. VIVIAN. Let me switch to a different, but related, question. On page 18, you have a list of the steering committee members.

Dr. GROBMAN. The original proposal to the National Science Foundation came from the American Institute of Biological Sciences, which is a national organization of biologists, and it selected a steering committee, and these members were included in the first proposal, I believe. This is no longer the same list, because people have rotated every year, you see.

Mr. VIVIAN. Does the selection of the steering committee or the other participants represent any conflict between yourself and the National Science Foundation?

Dr. GROBMAN. None, whatsoever.

Mr. VIVIAN. In other words, there is no dispute as to who the members would be or where the power of decision lay, and what members constituted that list?

Dr. GROBMAN. No. The NSF just wanted to be sure that there were competent and capable people, and there are certainly many such among that group, and that seemed adequate for the National Science Foundation's view.

Mr. VIVIAN. Referring to the appendix, have you received back from the Foundation a vacuum or a deluge?

Dr. GROBMAN. A vacuum.

Mr. VIVIAN. How much time has passed; 1 month?

Dr. GROBMAN. This was mailed out on the 14th of June; yes, sir.

Mr. VIVIAN. If we were to ask the people of NSF, do you think we would receive a vacuum?

Dr. GROBMAN. You would receive a deluge, I would think.

Mr. VIVIAN. I notice you have said you have received a contract from NSF for your efforts, and you have indicated that textbook revision efforts in other areas had received grants.

Dr. GROBMAN. If I said that, I was mistaken. We have been supported entirely by grants.

Mr. VIVIAN. The others have been supported entirely by grants?

Dr. GROBMAN. To my knowledge, yes.

Mr. VIVIAN. Who in the other subcommittees have written similar memorandums?

Dr. GROBMAN. For the other curriculum studies?

Mr. VIVIAN. Yes.

Dr. GROBMAN. I do not receive their memorandums, so I don't know. I would doubt there is any other. I think the reason is we are trying to do different things than the other.

Mr. VIVIAN. How many other curriculum groups are there?

Dr. GROBMAN. Oh, they are actually many, some very large like ourselves and some very small; many small ones. The NSF has published a list of these, a nice booklet.

Mr. VIVIAN. Have these other curriculum studies had similar funding periods and have they experienced any similar delays in the award of grants?

Dr. GROBMAN. I know that some of them have, from personal chats with directors.

Mr. VIVIAN. I would like to make a comparative study of this, Mr. Chairman, if resources are available.

Mr. DADDARIO. Information on other curriculum study groups supported by NSF will be obtained by the staff and furnished for the record. (See appendix, vol. II.)

Mr. VIVIAN. In terms of the effort that was put in, do you feel very confident that your documents were competently done by a unique process with excellent results?

(Dr. Grobman nodded affirmatively.)

Mr. VIVIAN. I have no reason to dispute this, and the acceptance thereof is probably a pretty good criteria.

Let me ask a question: Would 5 years be an adequate period for repeating this endeavor, or do you construe it as being a continuing endeavor, or do you think a different group of people should be involved?

Dr. GROBMAN. That is a moot point, because we do have a different group of people involved continuously. Our steering committee rotates one-third every year, for example, which changes our policies, sometimes drastically, sometimes subtly. We keep rotating people through our writing teams, and we rotate people through our staff. In fact, of our professional staff this year of nine people, I think eight will be leaving. It is a tremendous rotation.

I think the program should be continuous, because to get all the momentum started and to them cut it off and rebuild again would be a tremendous waste of time and money, and it would be difficult to recruit good people to start over again on something that has already been continuing.

Furthermore, there are many things that can be done between revisions of these major books. For example, many teachers, through no fault of their own, aren't really prepared to handle some of the finer points in some of the material in these books. We can't get them all to summer institutes; we can't get them all to briefing sessions. One of the things we would like to do is to prepare a series of nine films, each one taking one of the major topics in these books showing a good master teacher presenting it to a classroom.

This is something we could do very nicely between revisions of the books. There are other projects of that nature that could help the whole program contribute further, if we were sure we could essentially be a continuing organization.

Mr. VIVIAN. Could you continue at where you are now, at half, or more; maybe double?

Dr. GROBMAN. We were up to 2 million a year. We are down to 1.2 million. I think something in the neighborhood of 800,000 would be quite adequate for us, indefinitely.

Mr. VIVIAN. How much competition is there in the republishing of these textbooks? Suppose some firm which is not publishing textbooks wants to publish some?

Dr. GROBMAN. These are copyrighted.

Mr. VIVIAN. By whom?

Dr. GROBMAN. The American Institute of Biological Sciences.

Mr. VIVIAN. What has the policy of the——

Dr. GROBMAN. Our policy is to be extremely liberal, and we are glad to let any publisher who wants to use any of our materials in his book use 10 percent without any cost. This is an extremely liberal provision, but no publisher has yet taken advantage of it.

Mr. VIVIAN. All royalties are returned to the Federal Treasury?

Dr. GROBMAN. Yes.

Mr. VIVIAN. There is no question as to who is coming out ahead in terms of profits on the publication of a book?

Dr. GROBMAN. No money, no royalties accrue to the writers. They were paid a stipend for their work. All the earnings go to the NSF which I understand deposits them with the Treasury.

Mr. VIVIAN. You indicated you had some disputes with NSF regarding funds and administrative conditions. Many scientific groups that are having difficulties with, say, agency A proceed immediately to agency B. And for good reason. Did you ever ask NIH for funds to continue the endeavor or expand any facet of it?

Dr. GROBMAN. No.

Mr. VIVIAN. Was this because of what I will call being gentlemen or because you didn't think you would succeed?

Dr. GROBMAN. I think the main reason is we just didn't have the manpower available to conduct these explorations.

Mr. VIVIAN. Did you consider going to the Office of Education for these funds?

Dr. GROBMAN. We have asked the Office of Education for one grant for a teacher preparation activity, and we haven't received it.

Mr. VIVIAN. Did you ask the Office of Naval Research for any funds?

Dr. GROBMAN. We did debate that. Our policy committee decided we should not ask mission-oriented agencies for money because we felt our goal was not mission oriented. We didn't want to be under the obligation of including a certain amount of atomic energy or a certain amount of health or something of this sort. So we have only gone to what, in our lingo, are "pure" agencies.

Mr. VIVIAN. You indicated earlier that you thought the distinction between the Office of Education and the National Science Foundation is that some people wouldn't understand. What do you mean by this phrase?

Dr. GROBMAN. We were talking in a different context, not about the development of these materials, but rather in terms of an overall recommendation of the kind of curriculum program that should be

used, and if such a recommendation were to come from the Office of Education, I am sure that many school people, school administrators for obvious or devious reasons would say, oh, there is Government control, this is not what you want to do, the Government is trying to get into things, and it would be an awfully difficult public information education job to clarify the real situation I think.

Mr. VIVIAN. Why is it different with the National Science Foundation?

Dr. GROBMAN. Because the National Science Foundation is not, from its offices, announcing what are good or poor curriculums or making any recommendations whatsoever. The Foundation is merely supporting a group like the BSCS and the BSCS can succeed or fall on its face with no public evaluations from the NSF.

Mr. VIVIAN. If we were to combine the Office of Education and the National Science Foundation and relabel it the "National Education Commission," what would be the situation? I am trying to find out whether labels or substance is involved.

Dr. GROBMAN. If the Office of Education or the National Science Foundation were to support curriculum studies, I think there would be no problems, the problems would be extremely minor. But if either one of those organizations were to recommend a series of curriculums for the schools to use, then there would be great reaction.

Mr. VIVIAN. Does the Office of Education now recommend curriculums?

Dr. GROBMAN. No; it does not.

Mr. VIVIAN. So why should it make much difference?

Dr. GROBMAN. We were talking before about the question of whether there should not be some kind of national group recommending how these various curriculums could be used together and whether there were gaps in our coverage and things of this sort. Such a recommending agency should not be part of one of the present Federal agencies.

Mr. VIVIAN. Doesn't the NEA——

Dr. GROBMAN. That is a private organization.

Mr. VIVIAN. Doesn't it have a committee which has more or less this function?

Dr. GROBMAN. If it has, it is not very effective.

Mr. VIVIAN. If there is a deficiency in this particular zone, it should be in a sense laid to the private organization itself?

Dr. GROBMAN. No; I don't think that is right either.

Mr. VIVIAN. I said if there is a deficiency. But go ahead.

Dr. GROBMAN. Oh, there is a deficiency, I don't think there is any doubt about that. I don't think it should be a private organization because a private organization cannot be representative of the consumers of these materials.

Mr. VIVIAN. Why not? If it isn't private, it has to be public. And you said it shouldn't be public.

Dr. GROBMAN. No, I didn't. I said I don't think it should be one of the existing agencies. I don't know of any existing private agency that could do it. I think one way this could be done, this is outside the realm of my competence, but I throw this out as an interested citizen, one way this could be done is through a Presiden-

tial adviser on education with a good staff of people who could look at these curriculum studies, bring together groups to review them and other things, and then report to the President and say, "Based on our experience we find that one of the better ways to teach biology at the 10th grade is to use BSCS materials, it has this advantage and this deficiency." This Presidential adviser could also say, "We have explored the teaching of foreign languages and we find that the schools that are using beginning foreign languages in the elementary grades are doing a much better job than those that begin them in the secondary grades," or the reverse. Some kind of impartial recommendations coming from such an adviser I think would be of great benefit to the school people providing they didn't carry any kind of coercion or control.

Mr. VIVIAN. Do you think it is better if it comes out of the President's Office than if it comes out of the Office of Education?

Dr. GROBMAN. I think in the present climate it would be more acceptable; yes.

Mr. DADDARIO. Dr. Grobman, we only have a few more minutes, but in the time remaining, I wonder if you could touch on the effect that this work has had in foreign countries. You refer to that in your memorandum.

Dr. GROBMAN. Briefly, almost immediately when our materials were available, a number of our colleagues in foreign countries wanted to use them and translate them. We said, no, you can't translate them because the animals and plants in Peru are different than those here, or the educational system is different. You will have to adapt our materials before you can use them. This general policy has led to the establishment of adaptation committees of educators and biologists in a large number of countries, in Thailand, Japan, Taiwan, Argentina, Brazil, Colombia, and so on. We have had very many contacts with these people. We are helping them to develop new biology books for their own countries. The Philippine book is just off the press. It is the first biology book ever designed for Philippine conditions in their history, and I think it will be a wonderful contribution to science education in the Philippines. Much of the financial support for these programs has come from agencies like the Agency for International Development, the Asia Foundation, Rockefeller Foundation, very little from the National Science Foundation. It has been a very, very exciting, and satisfactory program except that we can't get enough funds to continue it on the level it should be conducted. I think it is a very useful thing because not only is it helping these countries to develop their scientific potentialities, but it is also establishing a kind of a person-to-person relationship among scientific colleagues without going through Government agencies in most instances. It is very satisfying on both sides.

Mr. DADDARIO. It is probably a relationship that has not existed through other international cooperative functions.

Dr. GROBMAN. It is a different kind of thing, yes.

Mr. BROWN. Mr. Chairman, could I have one short question?

Mr. DADDARIO. Why, of course.

Mr. BROWN. You mentioned your seeking of funds to prepare a series of films by master teachers. The next step in a course of this sort, it would seem to me, involves perhaps making these available on television, perhaps developing automated teaching of various sorts so that the effect of these courses can be disseminated on a much broader basis with a minimum amount of master teachers involved. Has additional thought been given to this rather pioneering aspect of the matter?

Dr. GROBMAN. Mr. Brown, we have given a lot of thought to that problem. First I should say there already exists a biology course on film that the AIBS put out about the time we started. That exists already. Our own feeling is that the best way for youngsters to learn science is by working in the laboratory or in the field. So we are, as a group, rather cool toward many of the audiovisual devices that a number of people are enthusiastic about today. These devices have a place, but it is not as large a place as their proponents would wish. So we have rather developed materials designed so that students could work in the laboratory and discover these things themselves rather than make them spectators of a film.

Mr. DADDARIO. Dr. Grobman, I want to thank you for coming. It has been a very interesting morning. We are limited by time in the extent of our questioning, but I hope we might be able to send some additional questions to you for the record.[1]

I want to apologize to Dr. Brady for not having had him appear this morning, but we will try to work that out for another time.[2]

We are happy to have had you here, Dr. Grobman.

Dr. GROBMAN. Thank you for inviting me here.

Mr. DADDARIO. This committee will adjourn until Tuesday next at 10 o'clock at the same place.

(Whereupon, at 11:30 a.m., the subcommittee was adjourned to reconvene at 10 a.m., Tuesday, August 3, 1965.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

[2] Dr. Brady has submitted a prepared statement to the subcommittee which will appear in the appendix, vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

TUESDAY, AUGUST 3, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

Our witness this morning is Dr. Jerome B. Wiesner. He is the dean of science at the Massachusetts Institute of Technology and former science adviser to the President. Dr. Wiesner has been a witness before this committee on many occasions, and a man whom we hold in highest regard.

We welcome you, Dr. Wiesner. I understand you do not have a prepared text and that you will give us the benefit of your informal advice.

STATEMENT OF DR. JEROME B. WIESNER, DEAN OF SCIENCE, MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Dr. WIESNER. I apologize for not having a prepared statement. Mr. Yeager asked me to participate in this hearing just before I left on a 5-week trip abroad, from which I have just returned, and I didn't want to have the pleasure of that trip spoiled by the necessity of worrying about preparing a statement. Instead, we agreed that I would be sent all the prepared statements presented to you, and when I got home I would read them and add anything which I believed had been left out.

So I have spent the weekend reading an enormous stack of testimony, which I presume you have all had the pleasure of reading and hearing elaborated. Practically anything that I can think of saying about the Science Foundation is contained in those documents, so it has been a bit hard for me to decide precisely what to do. I thought I would make some general observations based on my own observations of the NSF and then stress those matters discussed in the papers which I feel are particularly important and pertinent.

In your letter to me you also suggested that you would be interested in my observations about the general relationships of basic research in general, and of the Science Foundation's effort in particular to problems facing our Government and the problems of our Nation as a whole. I want to break the discussion into two pieces: First I would like to discuss the role of research in general in our society, and then

51-204—65—vol. 1——42

examine the role of the National Science Foundation within this particular framework.

I know that this committee on many occasions, and other committees of the Congress, too, has spent a great deal of time looking into the question of basic research and of technology in relation to our national security and economic development. As a matter of fact, this committee has stimulated discussions during the past 2 or 3 years with the result that there has been a tremendous increase in the understanding of the role of basic research to the technical development programs in this country and, as a matter of fact, I believe that as a result there has been a very great improvement in the understanding of this problem.

There has been, even among some scientists and engineers, a confusion about the complementary roles of science and technology, applied science and engineering, and the discussions of the last year or two I think have helped a great deal to clarify this in the mind of the Congress and the public as well as the practitioners.

There is no question at all that it is quite proper to regard doing basic research as an investment in the continued well-being and progress of our Nation. Scientists themselves may do research for other reasons—mostly because they like to work—but there would be no particular reason for the Nation making such very large investments in research if the only motivation was the esthetic one. At least we would then have strong arguments for making equal investments in the arts and music.

I think it is our confidence, based on past experience mostly, that the ever-increasing physical well-being of our Nation, our increasing affluence, is highly dependent on a continuous flow of knowledge about the universe. But when you try to get away from this very easily propounded generality, it gets a little harder to be specific about the facts. This is, of course, an important problem for us as a nation to face and one on which I spent a great deal of time when I worked as the President's science adviser. I know it is also one in which the committee has a continuing interest. That is, what is the proper level of research effort? What is the proper balance among the various possibilities? Who should make the decisions? How should the Government intervene? And what are the dangers of too much Government support?

These are the general social problems that we must be concerned with, and in a sense understand before we can become very specific about the role of the National Science Foundation in the total picture.

One of the most entertaining things that I did when I worked here in Washington—some of you have heard me talk about this before—was to try to get some feeling for what the proper level of research and development expenditures in this Nation should be. I believed that some of our time should be spent trying to achieve a judgment of whether what we were doing was right, whether we were spending too much money or too little, whether the Nation would be better off if we had more aggressive R. & D. efforts, and the White House group spent a fair amount of time trying to understand this question.

I talked with economists on the White House Council of Economic Advisers and others on many occasions, but I was not able to develop very specific criteria for answering these questions. I doubt if one can

really be very qualitative about these questions. It is, in a sense, a question with no answer, partially because of the nature of our society itself. Our society is not a planned system, in fact it is far from it. My own characterization of the society is that it is kind of a learning machine which learns by doing a lot of experiments, and you can't plan the experiments because the experiments are performed by a very large number of different people. Some succeed and some fail, and the Government is trying to participate in this process when it gets involved in the support of research or education or something else effecting the direction of the society. Since this is not a process that can be characterized with any high degree of precision, decisionmaking in any part of it obviously cannot be made extremely precise.

The economists were able to give me a sort of rule of thumb for research and development expenditures which would satisfy Congressman Vivian because of his engineering background or anyone else who has a mathematical background. They said that one should increase research and development expenditures until the resulting marginal increases in productivity equal the increased expenditures.

Now this is what in our business—electrical engineering—we would call an impedance matching process, and it is one which in electrical and mechanical systems is the way to get the maximum energy out of a power source, and it is also the condition which would provide maximum growth in our economy. All of this assumes, of course, that you can measure these things.

That is, of course, where the hitch comes. No one knows how to measure the contribution of a piece of basic research to economic growth. By and large, the things we do today depend on investments going back as far as over a hundred or more years, though largely during the past decade or two. In fact, this illustrates one of the most pleasant characteristics about scientific research; the information you gain is never obsolete. As you do gather more and more data, you know more and more about the world. You never need to do the same experiment over to learn the same fact.

Knowledge is investment that will last forever, and this fact makes it pretty hard to reach a judgment about the value of research as an investment. You certainly can't put a monetary price on the value of penicillin or the worth of jet-powered aircraft over piston craft. So really you can't go very far trying to be quantitative about the value of research.

However, you can get some feeling of the situation by asking how far from being at the condition mentioned earlier are we in our research investments. Here again you can get into some arguments because economists will not agree that all of the increase in productivity comes about as a result of research and development. In fact, they actually maintain that a larger share of it comes from enhanced training and education than from research and development. I would counter that the education would do no good if it were not for the more sophisticated society that technology makes possible. In any event, you can get an argument here.

I have estimated how much the marginal increases due to increased productivity amount to. If you assume that productivity is going up about 3 percent per year, you find an approximately $20 billion a year

increase in the GNP as a result of research and development. This is the total increase in productivity and is the result of all past R. & D. investments. I will arbitrarily attribute 15 percent or $3 billion of the increase to last year's increase in investments. This would indicate that one can afford very much larger increases in our R. & D. budget than the Nation has been making and still argue that it is a good investment.

In any event, I conclude that with a $2-billion-a-year basic research budget and spending in both the private and public sector approximately $20 billion a year total for both research and development, that we are nowhere near the point where increased expenditures would be a drain on our economy rather than a stimulant.

On the other hand, one can't generalize. There are obviously some expenditures which clearly will make a major contribution to economic growth and others which it is hard to be sure will have any effect.

So one shouldn't depend only on the economic justification. In fact, I want to be very careful not to give the impression that I believe that an area of basic research should be supported only if one can demonstrate that there is some likelihood of economic return, because the historical record shows that it is impossible to predict what areas of basic research are the ones that are going to turn out to have important practical consequences, and I think those people who propose—and there have been some proposals in the past, in fact, one was made to your committee last spring—that we make judgments about the way to allocate research money—basic research money—on the basis of our ability to guess about the possible importance of the outcome or the relevance of this research to related fields are making an extremely dangerous proposal. Furthermore, the intellectual value of the research must be considered.

There is a corollary, of course. If there is a field that is important to us and it requires basic research data to make something possible, as in the case of many space or military developments, we can certainly augment the supporting research effort. We often call such work applied research because we need the resulting information though the work itself might very well be characterized as fairly fundamental. But in those fields where our motives are not clear, we shouldn't try to guess ahead.

What I am saying is I think the Nation is in a position to profit from continual high-level research expenditures and, I believe, from increasing research expenditures.

We know that R. & D. expenditures increase at the rate of about 15 percent per year. This has been so, on the average, for the past decade and a half. I doubt whether we can afford to allow the total research and development expenditure to go on increasing at that rate for many years. When I worked down here in Washington, a member of the staff said one day that he could prove to me that the President had to be a scientist in 1984.

I said, "How are you going to do that?" He showed me a curve of the gross national product and the research and development expenditures, and by fudging just a little bit he got them to cross by 1984.

So it is very clear that this rate of growth in R. & D. expenditures cannot continue indefinitely. In fact, during the past year we have seen a very substantial reduction in the rate of growth in the develop-

ment programs, which I think is reasonable, particularly in the defense fields, where we now have a much better understanding of what we are doing than we did a few years ago.

In the basic research areas the Government's policy—that is, the administration's policy which I hope the Congress will support—is to see that basic research continues to grow at approximately 15 percent a year. I am not convinced that even that is enough, and I will tell you why in a few minutes.

The questions of balance between the Science Foundation and the other agencies, once you have established a national policy, also presents some difficulty. In most of the documents I submitted to you that I have seen the point is made that the Science Foundation's share of basic research support is probably too small.

I concur with this view; that is, the NSF share of the total Federal basic research effort is not great enough to allow it to be the dominant factor in policy determination that it ought to be nor can it provide adequate national leadership. But after saying this I would like to make it very clear that I do not think that other agencies should not support basic research for a variety of reasons.

I think the quality of mission-oriented activities in agencies would suffer very greatly if they were not involved in basic research—suffer because they wouldn't have as good people on their staffs, suffer because their relationships with academic and nonprofit and industrial research organizations would be poorer, so that I feel it is vital that the Defense Department, AEC, NASA, Interior, HEW, and other groups continue to be an important factor in the support of basic research, but I believe that in the future one should provide additional support in such a way that the Science Foundation does become a more important factor.

There is another point here which I know some of you have heard me make before. I am an anarchist at heart, at least I believe in insuring the possibility of multiple activities in our society. As I said earlier, I believe our form of society is one that encourages experimentation by a variety of people, and that we make our progress by trying things and recognizing errors.

I am convinced that competition is vital in basic research as well as in the economic aspects of our country. To have several agencies able to support interesting activities is an important ingredient in our society. If we don't want to end up with too much bureaucratic control and a kind of slow responding scientific support that we find many other countries suffering from and trying to get away from we should fight very hard to preserve the multiplicity of support.

I know that many people who have testified before this and other congressional groups don't agree with me and would like to see a Department of Science with strong control of all the Federal funds. Although superficially this might appear to be more efficient, I think it would be a very bad mistake.

For all these reasons, while I would support increasing the ratio of the NSF's share of the Federal budget in basic research over what it is now—I gather it is about 14 percent—some of the people who have talked before have suggested something like 25 percent, I don't know whether that is the right figure; it certainly shouldn't be 80 percent and I think 14 percent is too low. One can start to let it grow—in fact,

I gather this is happening—and watch it and see when we believe that we have reached a healthy balance.

There are a number of other points that were made in discussing the role of the Science Foundation, specific points, which I would like to pick up. These are essentially in the order in which I took them down as I made notes in reading the documents, rather than in a logical order or order of importance.

One of the most serious problems that the Foundation and the Government has faced in recent years has been the question of the geographic distribution of research support. During the past 5 or 6 years there has been a growing recognition around the country and in the Congress, and in the rest of the Government, and particularly in the Science Foundation, that the economic well-being of the various geographic areas is related to the existence of a good strong technological base, and that we have to do something to insure that such a base is available in all areas.

Those of us who had the executive responsibility for trying to do this were also concerned lest we hurt many good things that already exist. For instance, we felt that in the Defense Department it was important that the basic criterion for the allocation of Federal moneys, particularly in development but also in research supported by the Defense Department, should remain that of getting the maximum amount of national security for our expenditures. Where this is consistent with the objective of area development, one can certainly push in that direction.

We also feared the consequence of allocating the moneys of the NIH and the NSF on some geographic basis because we felt that the primary criterion should remain the promise of the proposed work.

But there have evolved a series of additional programs both in the Science Foundation and in the Office of Education aimed at trying to build up better competence; that is, to increase the number of first-rate research and teaching institutions in the country, and I believe that these relatively minor programs, minor on a national scale, have proved that these concepts are good, and it would seem to me it would be useful to push these, and push them very hard.

I would like to add an aside here. Many people have been impatient about the relatively slow rate of growth of the National Science Foundation as compared to other research and development activities in the country and when one considers, for example, that NASA was created in about 1958 and now has a $5 billion a year budget to support work in a rather relatively limited field and that the Science Foundation, created almost two decades ago, has only about 10 percent of this budget to support a vast variety of scientific fields, you can see some justification for this concern.

The National Institutes of Health budgets have also grown more rapidly. Some people claim that the Board of the Foundation has been too timid. I suspect that on occasions they have been.

Some people believe that the management of the NSF should have been more aggressive. But in the fact the extent to which Federal activities will be supported depends largely on what the executive branch, the President is willing to do, and particularly what Congress is willing to do. And because the Science Foundation, until it became deeply involved in educational research and development, had

no mission-oriented activities, it found it hard to convince the executive branch of the Government that it should grow rapidly. Furthermore, because it had no mission-oriented responsibilities, it did not receive strong congressional support, at least not like the groups that were responsible for space, atomic energy, or military developments.

One shouldn't lose sight of how important the congressional understanding and support of these activities is and has always been. The reason that we have had a very good and strong atomic energy program is easily traceable to the interest and activities of the Joint Committee on Atomic Energy. I think that the interest of the Congress in space activities, the early hearings, and the continued interest of your group, has been an important factor in the understanding and support there has been for our space program.

Until recently, at least, this kind of understanding and support for basic research and particularly for the activities of the Science Foundation has been lacking. I hope that the interest that you show now is just the beginning of a continuing involvement in basic research in this country, and particularly a fuller recognition of the important role of the Science Foundation in our scientific activities.

Just to go on with the points that I found in the documents, several people raised the problem of increasing control, redtape, and bureaucracy, not only in the NSF, but in all the agencies that are involved in support of science, and I think this is a fact. This is a result first of all of the fact that the sums of money are larger, therefore the concern about the proper use and effective use has been growing, but also because there has been a feeling on the part of some people in Congress, but I must add not in this particular group, that you can deal with research in the same way that you can deal with procurement, and you can't.

You can set up controls which attempt to find out what people are doing, which attempt to keep track of their time, and you can in fact create a very efficient accounting system, but the net result of this most likely will be merely to slow down and frustrate research activity rather than to improve it.

Certainly universities and the large corporations that support research believe that the maximum degree of flexibility and freedom in choosing programs and changing them is the way to insure the most effective use of their money. And I would suggest that it would be extremely useful for this group at some time, I won't go further into the point, to dig into this question and to see whether the trend toward growing bureaucracies in our support of science can't be reversed and still provide a situation that is consistent with the responsibilities which both the executive branch and the Congress must exercise in the use of funds.

Part of the paperwork problem has come about as a result of fiscal considerations; that is, there have been periods when the support for basic research didn't grow as rapidly as the demand for funds was growing. But during the late fifties, for example, when the basic research budgets such as the Science Foundation budget were held level, crisis was avoided by shortening the term of grants.

There was a time when grants were made for 3 years, and then they were shortened to 2 years and even 1 year. We have not recovered completely from a situation where some grants could only be made for

1 year because funds were so limited. This by itself increased the amount of paperwork since research workers had to apply for grants each year instead of once every 3 or 5 years. This involved them in more proposal writing, more negotiating with the sponsoring agencies and also produced more uncertainty on the projects. Furthermore the agencies have to deal with three times as many proposals if they make grants for 1 year rather than 3 years.

The magic number, 15 percent per year, is worth some examination.

First of all, there is sort of a natural or internal rate of growth of scientific activities, if one lets an activity run by itself without putting any restraints on it, or at least no restraints other than the requirement that what people want to do be justified on the basis of the scientific worth of the activities.

Then, I suppose, largely as a result of the rate at which one can educate new scientists and the rate at which one can build equipment and do experiments, there is sort of a natural limit that is pretty close to the 5-year doubling time which we have been living with.

Furthermore as long as activities are growing fast, most of the people doing research will be young people, and this is probably good because young people are the most creative people. But this also means that they are in the stage of their career where their salaries are increasing rapidly. I would suppose that nationwide, in industry and in universities, the salaries of the bulk of the scientists and engineers are increasing at approximately 5 percent per year.

Then there is a certain degree of inflation, which seems to be larger in the technical community than in the Nation as a whole. Certainly the cost of living has not been going up very rapidly in the last 3 or 4 years, but the cost of scientific activities do still increase. The technicians' cost seem to go up, the apparatus we use get more and more costly. As fields get developed and more and more sophisticated, the questions that are asked require more elaborate tools, and the costs go up for that reason.

All of these factors are involved in the 15 percent per year growth. There is very little we can do about this if we are prepared to accept the criterion which I proposed we do for at least the next few years; that is, to support those good basic research activities.

Mind you, I am saying basic research, I am not saying applied research or technology. There I think one has to look much more carefully at the purposes and be sure that proposed investments are worth making.

The documents reflect the pet hobbies of some of the witnesses, and I have some of my own. There are some specific areas which people feel have been neglected and which, I am certain, cannot be funded properly even if the 15 percent per year increase in basic research in the Foundation is continued.

Several people, Dr. Walker and several others, complained, and I think that is the right word for their statement, about the fact that engineering research has not been adequately supported by the Foundation.

I think that is probably true, but I think the fault lies not so much with the Foundation as with engineering community in its failure to recognize just what should be done and to come forward with adequate programs.

I believe that it is very important to try to do something about this for several reasons. First of all, I think there are a number of important national problems to which engineering research could make a major contribution and which are not as likely to be adequately handled by commercial interests or governmental activities. They might be done by Government, but I think they can be enhanced by stimulating activity in the universities, in the public sectors, which I am sure you are all familiar with, such as pollution control, more efficient medical engineering, atmospheric measuring equipment, oceanography, getting more and cheaper water-system engineering in transportation and city planning, and so forth. These are fields where large-scale research in engineering techniques could make a major contribution and in which the universities and engineering schools have had very little involvement. I think more basic research here would make a major contribution.

There is another very important reason for supporting these areas—I have only listed a few, I could list housing, urban development with proper kind of planning, maritime developments—not only would we benefit from the knowledge we gain in these fields, but I think the kind of engineering activities that have gone on in universities and in engineering schools have distorted our engineering community by creating specialized interests for the graduate students.

People tend to want to continue in the kind of research or development activity that they started in their graduate education and research activities.

Because of the problems the Nation faced during the past two decades—for a great many of us these activities were largely in the military field—engineers become particularly competent in advanced electronics, aerodynamics, radar technology, communications, and similar specialized fields. They are important, and we should go on supporting them.

On the other hand, we haven't been turning out a group of young people who are interested in and excited about some of the other very important problems, and I think we could give a tremendous stimulus to these fields and to the national economy by supporting the universities in these fields, encouraging them to do such engineering research.

So I would think that the Science Foundation should try to develop a stronger program in the engineering sciences than it has had.

You have heard much during these discussions about the educational activities of the National Science Foundation, the development of new curriculums and so on, and I think these are very good. I have been impatient about the fact that we are not doing more in these fields. I think the opportunities far exceed the accomplishments to date in the development of better educational methods and better science teaching programs. The possibilities extend far beyond the possible contributions to education in science to education in general.

I think there are contributions to be made by this kind of research and development to the whole field of education, and the work is badly needed. So I would encourage a considerable enhancement in these activities.

I think that the behavioral sciences have been inadequately funded by the Nation, not only by the Science Foundation but by all of the

agencies in the Government. This situation has been improving in recent years, the Science Foundation has been trying to do something about it and so have the National Institutes of Health, but I think that in a society which is so dependent on understanding of the relationship between the human being and the society on other human beings, we are not really spending enough money in these fields.

I would include in this group the broad field of the communication sciences, economics, the behavioral sciences, and the social sciences. The question of what is appropriate for the National Science Foundation to support and where to draw the line has never been resolved. There has been great reluctance to have the NSF support social science research, but unfortunately there doesn't seem to be any other group that can provide broad general basic support for this important area, and failing to find one or create one, I believe it is better to ask the Science Foundation to broaden its range of interest and support them strongly rather than to continue the past neglect.

A serious problem for the Nation, and particularly for the universities—and here you must recognize that I have a vested interest—is the need to use computers extensively in the educational process. The use of computers in research and the rapidly increasing use of computers in education, particularly in science and engineering education, has created a considerable crisis in American universities, of which you may already be aware though I didn't see it mentioned in the documents I received.

The use of computers in universities is growing at about twice the rate of their research and development activities, and consequently almost every substantial engineering school and school of science is at the point where it can no longer afford adequate computational facilities. Every school that I know well, including MIT, is involved in a series of maneuvers involving ad hoc arrangements to keep its computational activities solvent and to provide some time for academic use.

Without very substantial increases in tuition or other sources of funds to pay for computer time, schools will not be able to an adequate job of educating scientists and engineers to do their work in the most efficient way; that is, with computers.

I don't know precisely what should be done about this. Last year I looked into this problem and made an estimate of the need. Two things are required. Many schools need means of acquiring additional computational facilities. In this respect MIT happens to be fortunate, but there are very many other universities and engineering schools in the country that are inadequately equipped with computers.

Some means should be devised to provide them with better computational facilities. Second, there is a need to provide fiscal support for the academic on teaching uses of computers. I really don't know how this should be done. Possibly this is not a task for the National Science Foundation. Perhaps the Office of Education should have the responsibility for this, though most of the immediate opportunity in education is in the field of science and engineering.

I think this is probably the most serious single special problem in higher education—aside from the normal needs for buildings and so on—which I am sure you know all about, the most serious single problem confronting scientific and technical schools.

Many people, in their statements, make the observation that several traditional fields are undersupported or underequipped. I believe that is actually true. One can readily demonstrate this in the fields of chemistry and mathematics, and it is probably true in the new fields, the emerging fields such as the environmental sciences, but I think you have so much testimony on this subject that I needn't say any more about it.

There is another group of educational problems that I would like to see the Science Foundation do a great deal more about than it has in the past, and those are the special problems the small colleges have in the teaching of science. There are literally hundreds, maybe as many as a couple of thousand small colleges and junior colleges, schools not interested in giving professional education in science, but who should do a reasonably good job of teaching elementary and intermediate science if we are ever to have citizens with some understanding of what science is all about, something I regard as important in our modern society, and if we are going to be sure that students in these schools with an aptitude for doing creative research or engineering receive an education that both stimulates them and makes it possible for them to go on.

This is not the case today in too many of these small schools and they need a lot of help with equipment, staff, and curriculum development. We should develop special courses that can be taught well in spite of the limited facilities available in these schools. The Federal Government should consider providing special facilities to support, and even some way of supporting science faculties in these schools.
